Science in Islamic philosophy

Islam attempts to synthesize reason and revelation, knowledge and values, in its approach to the study of nature. Knowledge acquired through rational human efforts and through the Qur'an are seen as complementary: both are 'signs of God' that enable humanity to study and understand nature. Between the second and eighth centuries AH *(eighth and fifteenth centuries* AD*), when Muslim civilization was at its zenith, metaphysics, epistemology and empirical studies of nature fused to produce an explosion of 'scientific spirit'. Scientists and scholars such as Ibn al-Haytham, al-Razi, Ibn Tufayl, Ibn Sina and al-Biruni superimposed Plato's and Aristotle's ideas of reason and objectivity on their own Muslim faith, thus producing a unique synthesis of religion and philosophy. They also placed great emphasis on scientific methodology, giving importance to systematic observation, experimentation and theory building.*

Initially, scientific inquiry was directed by everyday practices of Islam. For example, developments in astronomy were influenced by the fact that the times of Muslim prayer were defined astronomically and its direction was defined geographically. In the later stage, the quest for truth for its own sake became the norm, leading to numerous new discoveries and innovations. Muslim scientists did not recognize disciplinary boundaries between the 'two cultures' of science and humanities, and individual scholars tended as a general rule to be polymaths. Recently, Muslim scholars have started to develop a contemporary Islamic philosophy of science by combining such basic Islamic concepts as 'ilm *(knowledge),* khilafa *(trusteeship of nature) and* istisla *(public interest) in an integrated science policy framework.*

1 Science and metaphysics

The Muslim inspiration for the study of nature comes straight from the Qur'an. The Qur'an specifically and repeatedly asks Muslims to investigate systematically natural phenomena, not simply as a vehicle for understanding nature but also as a means for getting close to God. In Surah 10, for example, we read:

> He it is who has made the sun a [source of] radiant light and the moon a light [reflected], and has determined for it phases so that you might know how to compute years and to measure [time]…in the alternative of night and day, and in all that God has created in the heavens and on earth, there are messages indeed for people who are conscious of Him.
>
> (Surah 10: 5-6)

The Qur'an also devotes about one-third of its verses to describing the virtues of reason. Scientific inquiry, based on reason, is thus seen in Islam as a form of worship. Reason and revelation are complementary and integrated methods for the pursuit of truth.

The philosophy of science in classical Islam is a product of the fusion of this metaphysics with Greek philosophy. Nowhere is this more apparent than in Ibn Sina's theory of human knowledge (see Ibn Sina §3) which, following al-Farabi (§3), transfers the Qur'anic scheme of revelation to Greek philosophy. In the Qur'an, the Creator addresses one man - the Prophet - through the agency of the archangel Gabriel; in Ibn Sina's Neoplatonic scheme, the divine word is transmitted through reason and understanding to any, and every, person who cares to listen. The result is an amalgam of rationalism and ethics. For Muslim scholars and scientists, values are objective and good and evil are descriptive characteristics of reality which are no less 'there' in things than are their other qualities, such as shape and size. In this framework, all knowledge, including the knowledge of God, can be acquired by reason alone. Humanity has power to know as well as to act and is thus responsible for its just and unjust actions. What this philosophy entailed both in terms of the study of nature and shaping human behaviour was illustrated by Ibn Tufayl in his intellectual novel, *Hayy ibn Yaqzan*. Hayy is a spontaneously generated human who is isolated on an island. Through his power of observations and the use of his intellect, Hayy discovers general and particular facts about the structure of the material and spiritual universe, deduces the existence of God and arrives at a theological and political system (see Epistemology in Islamic philosophy; Ethics in Islamic philosophy).

While Mu'tazilite scholars had serious philosophic differences with their main opponents, the Ash'arite theologians, both schools agreed on the rational study of nature. In his *al-Tamhid*, Abu Bakr al-Baqillani defines science as 'the knowledge of the object, as it really is'. While reacting to the Mu'tazilite infringement on the

domains of faith, the Ash‘arites conceded the need for objective and systematic study of nature. Indeed, some of the greatest scientists in Islam, such as Ibn al-Haytham (d. 1039), who discovered the basic laws of optics, and al-Biruni (d. 1048), who measured the circumference of the earth and discussed the rotation of the earth on its axis, were supporters of Ash‘arite theology (see Ash‘ariyya and Mu‘tazila).

The overall concern of Muslim scientists was the delineation of truth. As Ibn al-Haytham declared, ‘truth is sought for its own sake’, and al-Biruni confirmed in the introduction to his *al-Qanun al-mas‘udi*: ‘I do not shun the truth from whatever source it comes.’ However, there were disputes about the best way to rational truth. For Ibn Sina, general and universal questions came first and led to experimental work. He begins his *al-Qanun fi'l-tibb (Canons of Medicine)*, which was a standard text in the West up to the eighteenth century, with a general discussion on the theory of drugs. For al-Biruni, however, universals came out of practical, experimental work; theories are formulated after discoveries. But either way, criticism was the key to progress towards truth. As Ibn al-Haytham wrote, ‘it is natural to everyone to regard scientists favourably…. God, however, has not preserved the scientist from error and has not safeguarded science from shortcomings and faults’ (see Sabra 1972). This is why scientists so often disagree amongst themselves. Those concerned with science and truth, Ibn al-Haytham continued, ‘should turn themselves into hostile critics’ and should criticize ‘from every point of view and in all aspects’. In particular, the flaws in the work of one's predecessors should be ruthlessly exposed. The ideas of Ibn al-Haytham, al-Biruni and Ibn Sina, along with numerous other Muslim scientists, laid the foundations of the ‘scientific spirit’ as we have come to know it.

2 Methodology

The ‘scientific method’ (see Scientific method), as it is understood today, was first developed by the Muslim scientists. Supporters of both Mu‘tazilism and Ash‘arism placed a great deal of emphasis on systematic observation and experimentation. The insistence on accurate observation is amply demonstrated in the *zij*, the literature of astronomical handbooks and tables. These were constantly updated, with scientists checking and correcting the work of previous scholars. In medicine, Abu Bakr Muhammad al-Razi's detailed and highly accurate clinical observations in the early third century AH (ninth century AD) provide us with a universal model. Al-Razi was the first to observe accurately the symptoms of smallpox and described many ‘new’ syndromes. However, it was not just accurate observation that was important; equally significant was the clarity and precision by which the observations are described, as was demonstrated by Ibn Sina in his writings.

The emphasis on model construction and theory building can be seen in the category of Islamic astronomical literature known as *‘ilm al-haya*, or ‘science of the structure (of the universe)’, which consists of general exposition of principles underlying astronomical theory. It was on the strength of both accurate observation and model construction that Islamic astronomy launched a rigorous attack on what was perceived to be a set of imperfections in Ptolemaic astronomy (see Ptolemy). Ibn al-Haytham was the first to declare categorically that the arrangements proposed for planetary motions in the *Almagest* were ‘false’. Ibn Shatir (d. 1375) and the astronomers at the famous observatory in Maragha, Adharbayjan, built in the thirteenth century by Nasir al-Din al-Tusi, developed the Tusi couple and a theorem for the transformation of eccentric models into epicyclic ones. It was this mathematical model that Copernicus used to develop his notion of heliocentricity, which played an important part in the European ‘scientific revolution’.

Apart from the exact sciences, the most appropriate and interesting area in which theoretical work played an essential role was medicine. Muslim physicians attempted to improve the quality of *materia medica* and their therapeutic uses through continued theoretical development. Emphasis was also placed on developing a precise terminology and ensuring the purity of drugs, a concern that led to a number of early chemical and physical procedures. Since Muslim writers were excellent organizers of knowledge, their purely pharmacological texts were themselves a source for the development of theories. Evolution of theories and discovery of new drugs linked the growth of Islamic medicine to chemistry, botany, zoology, geology and law, and led to extensive elaborations of Greek classifications. Pharmacological knowledge thus became more diversified, and produced new types of pharmacological literature. As this literature considered its subject from a number of different disciplinary perspectives and a great variety of new directions, there developed new ways of looking at pharmacology; new areas were opened up for further exploration and more detailed investigation. Paper-making made publication more extensive and cheaper than use of parchment and papyrus, and this in turn made scientific knowledge much

more accessible to students.

While Muslim scientists placed considerable faith in scientific method, they were also aware of its limitations. Even a strong believer in mathematical realism such as al-Biruni argued that the method of inquiry was a function of the nature of investigation: different methods, all equally valid, were required to answer different types of questions. Al-Biruni himself had recourse to a number of methods. In his treatise on mineralogy, *Kitab al-jamahir (Book of Precious Stones)*, he is the most exact of experimental scientists. However, in the introduction to his ground-breaking study *India* he declares that ‘to execute our project, it has not been possible to follow the geometric method’; he therefore resorts to comparative sociology.

The work of a scholar of the calibre and prolificity of al-Biruni inevitably defies simple classification. He wrote on mineralogy, geography, medicine, astrology and a whole range of topics which dealt with the dating of Islamic festivals. Al-Biruni is a specific product of a philosophy of science that integrates metaphysics with physics, does not attribute to either a superior or inferior position, and insists that both are worthy of study and equally valid. Moreover, the methods of studying the vast creation of God - from the movement of the stars and planets to the nature of diseases, the sting of an ant, the character of madness, the beauty of justice, the spiritual yearning of humanity, the ecstasy of a mystic - are all equally valid and shape understanding in their respective areas of inquiry. In both its philosophy and methodology, Islam has sought a complete synthesis of science and religion.

Polymaths such as al-Biruni, al-Jahiz, al-Kindi, Abu Bakr Muhammad al-Razi, Ibn Sina, al-Idrisi, Ibn Bajja, Omar Khayyam, Ibn Zuhr, Ibn Tufayl, Ibn Rushd, al-Suyuti and thousands of other scholars are not an exception but the general rule in Muslim civilization. The Islamic civilization of the classical period was remarkable for the number of polymaths it produced. This is seen as a testimony to the homogeneity of Islamic philosophy of science and its emphasis on synthesis, interdisciplinary investigations and multiplicity of methods.

3 Revival attempts

At the end of the twentieth century, scholars, scientists and philosophers throughout the Muslim world are trying to formulate a contemporary version of the Islamic philosophy of science. Two dominant movements have emerged. The first draws its inspiration from Sufi mysticism (see Mystical philosophy in Islam) and argues that the notions of ‘tradition’ and the ‘sacred’ should constitute the core of Islamic approach to science. The second argues that issues of science and values in Islam must be treated within a framework of concepts that shape the goals of a Muslim society. Ten fundamental Islamic concepts are identified as constituting the framework within which scientific inquiry should be carried out, four standing alone and three opposing pairs: *tawhid* (unity), *khilafa* (trusteeship), *‘ibada* (worship), *‘ilm* (knowledge), *halal* (praiseworthy) and *haram* (blameworthy), *‘adl* (justice) and *zulm* (tyranny), and *istisla* (public interest) and *dhiya* (waste). It is argued that, when translated into values, this system of Islamic concepts embraces the nature of scientific inquiry in its totality; it integrates facts and values and institutionalizes a system of knowing that is based on accountability and social responsibility. It is too early to say whether either of these movements will bear any real fruit.

Science, 19th century philosophy of

In the nineteenth century, science was organized, it tested and confirmed positive knowledge of the natural world and achieved remarkable theoretical development and hitherto unimagined practical application. Science drove industry and free enterprise, and became a powerful catalyst in the battle between defenders of knowledge as power and advocates of knowledge as love.

Fruitful scientific theories and observations were plentiful. Darwin, Wallace and Spencer caused a revolution in biology. Faraday, Maxwell and Hertz contributed seminal ideas in electromagnetic theory. Hermann von Helmholtz studied the physiology of tones and discovered a principle of the conservation of force. Lyell's efforts established geology as a science. Ernst Mach argued for the elimination of absolute space in favour of a space and time consisting of observable relations between things, thus providing incentive for Einstein's theory of relativity. Sir John Herschel added many observed double stars to the growing catalogue of celestial bodies.

These and other observational, theoretical and applied achievements in nineteenth-century science were replete with philosophical consequences. Until the nineteenth century natural philosophy and science coexisted as a single discipline. Now science and traditional philosophy drew apart. Some held that henceforth science would deal with the world revealed in experience, and philosophy with the world existing (if any does) beyond what we experience. Others (including prominent scientists) were unwilling to yield to philosophy licence to speculate beyond the limits of what could be ascertained by means of observation and experimentation: even if science and philosophy were no longer one unified intellectual enterprise, philosophy had a substantial role to play in philosophizing about science.

To satisfy changing expectations, a new intellectual discipline was created in the nineteenth century: the philosophy of science. Unlike previous philosophy, whose subject matter was everything that is (or is not), the philosophy of science had a distinct and determinate subject matter: theoretical texts and experimental and observational reports of scientists (the word 'scientist' having been invented by William Whewell).

Theoretical scientific systems and their logical structure were one focus of attention. Science was also said to discover laws. Were such laws timeless and exceptionless truths about nature, or simply convenient, economical ways of cataloguing information? These laws were discovered (or invented) generalizations that provided tested information about nature. This discovery and confirmation relied upon the method of induction - thought by most nineteenth-century philosophers of science to have a logic - to involve decisions concerning the validity or invalidity of inferences based on knowledge from experience. Was this alleged logic trustworthy? These questions exemplify the complex problems concerning the epistemic reliability of scientific explanation.

1 'Man is the interpreter of nature, science, the right interpretation'

William Whewell provides the aphoristic watchword expressive of the new nineteenth-century preoccupation with the success of science. For him, as for many others, certain fundamental scientific theories had achieved the status of complete and unrevisable truths, among them, the physical synthesis of Newton and the wave theory of light. These theories stood as exemplars of what could be achieved in the inductive natural sciences. Study of the historical development of these, and other, sciences reveals the methodological strategies involved in the establishment of theories now seen to be established truth. Above all, the history of the inductive sciences confirms that science is progressive, moving always towards theories that are simpler, more comprehensive and more accurate as instruments of prediction. New sciences may emerge, but the established ones now require, not additional evidential support, but only refinement.

Others, like Ernst Mach, pointed out that the major theoretical triumphs of science should be construed as invitations to strive for completion, for the end of a science is an ideal, not an achievable result. Nevertheless, Mach shared the general acceptance of the fact that science is progressive, that what we know of nature now is somehow more reliably known than heretofore. A completed science may never be attained but this admission need not entail that we have not progressed in our positive knowledge of how the world works.

John Stuart Mill argued for the epistemic ascendancy of science by claiming that because science has discovered some invariable laws of nature, we can justly conclude that all phenomena are governed by such laws. The

progress of science is characterized by the discovery of lawfulness.

Progress as completion of theory, as epistemic ideal, as discovery of laws - three complex philosophical versions of the Victorian aphorism: nature as text receives its best reading from the precise and comprehensive testimony of science.

2 ‘The general property of the age’

John Stuart Mill used this phrase to describe what Auguste Comte conceived as the concluding phase of human cultural history: entry into a positivistic age in which both religion and metaphysics no longer function as reliable guides to human action. That which transcends human experience is to be replaced forever by a cooperative social reliance upon the facts disclosed by the sciences.

Many of the thinkers of the century can be classed as positivists, not in the sense of those in the Vienna Circle (see Logical positivism §4; Vienna Circle) but in the sense of subscribing to the main tenets of a new, although not always explicitly articulated, philosophical programme involving five commitments. First, Victorian positivists accepted Whewell’s aphorism: only science provides reliable knowledge of nature. Second, these philosophers were convinced that metaphysics could no longer be regarded as a trustworthy source of knowledge. Third, for the majority of nineteenth-century philosophers it was almost a truism to hold that, whatever is to count as reliable knowledge must make contact with the world of human experience. Whewell’s ‘facts’, Mach’s ‘elements’, Mill’s ‘particulars’ and Helmholtz’s ‘perceptions’ (see Helmholtz, H. von §2) form a family of conceptualizations of meaningful human experiences. For these thinkers (Mill may be the exception) the basic units of experience are laden with theory. Whewell’s facts come about by means of the controlled imposition of an idea upon given data. Mach’s elements are creatures of reflection upon common human episodes. Helmholtz’s perceptions are produced by unconscious inferences based upon rememberings. Nevertheless, the implications of an idea can be tested, an abstraction can be decomposed into its participating components and an inference can be found to be valid or invalid. The point is that, if illusions and imperfect conceptual constructions can somehow be accounted for, it will have to be agreed that no legitimate knowledge can proceed from a foundation other than what is directly available in human contact with the environment.

Fourth, mathematics was elevated to a high position both in education and in the work of scientists. The arguments on behalf of the primacy of mathematics came from Whewell and his contemporaries at Cambridge, later from Henri Poincaré, and from the new formal logicians, for example Stanley Jevons, George Boole and Augustus DeMorgan. Fifth, an element of pragmatism became prominent in the thinking of philosophers of science. Part of what is typical of the application of scientific inductive method involves the making of decisions based on considerations of utility, workability and other values not necessarily associated with truth.

Nineteenth-century philosophers of science did not engage the five points as planks in a philosophical platform. There were important exceptions. Not everyone developed an ambiguity-free positivism of the sort described. What is involved is not so much intellectual acceptance of a set of propositions; rather, our philosophers of science in the main assumed the five points as philosophical obligations, matters of trust to be taken to heart if one is to understand science. From a historical perspective the five points ought to be construed as sign posts directing the investigation of how philosophers of the nineteenth century understood science.

3 The status of scientific laws

In an age of sociopolitical empires, when half the known world was being cut up piecemeal by piratical European governments, it was not difficult for philosophers to call attention to the universal tendency of human beings to generalize, to project universal claims on the basis of small samples. Ever since Aristotle, such generalization had been identified as induction. The formula, though vacuous as a classification, persisted: deduction moves from the general to the particular; induction, from the particular to the general (see Inductive inference; Logic in the nineteenth century). Whewell and Sir John Herschel believed they had discovered an inductive ‘propensity’. Herschel characterized this tendency as an

> irresistible impulse of the mind to generalize *ad infinitum*, when nothing in the nature of limitation or opposition offers itself to the imagination, [and as an] involuntary application of the law of continuity to fill up, by the same ideal substance of truth, every interval which uncontradicted experience may have left blank in our

inductive conclusions.

(1857a: 198)

Whewell was also convinced that ‘ the mind has a perpetual propensity to consider… individual propositions as cases of more general ones and to frame and contemplate these latter’ (1830).

In one of his notebooks, Whewell illustrates this propensity by means of a humorous, if logically badly flawed, example:

[We start with the particular observation that:]

(1) That apple tree is full of fruit;

[and then move from this observation through the following generalizing steps:]

(2) All apple trees of this district are full of fruit;
(3) All the fruit trees of the kingdom are this season full of fruit;
(4) This season is one of great fruitfulness;
(5) All things are at present going on very well;

[to this grand generalized conclusion:]

(6) All things always go on well[!]

(1830)

This propensity provides the nerve centre of inductive logic. The conclusions of generalizing, which in common affairs are maxims or rules of behaviour, in the sophisticated reaches of scientific inference, are laws. For most philosophers of science a law represents a proposition expressing universally invariant regularity of some sort, and possessing what is now called ‘counterfactual force’ (see Counterfactual conditionals; Laws, natural §2). Even if no piece of lead is ever again submerged in *aqua regia*, it is still true that ‘lead dissolves in *aqua regia*’.

Mill and Whewell, believing as they did that the logic of induction possesses resources for distinguishing valid from invalid inductive inferences, held also that the results of valid inductions, laws, are necessary truths. Herschel provided the conceptual flag carried by the growing regiment of scientific realists who regarded the observed regularities as fixed, ‘ the laws of nature are not only permanent, but consistent, intelligible, and discoverable with such a modest degree of research, as is calculated rather to stimulate than to weary curiosity’ (1830) (see Scientific realism and antirealism §1). Whewell argued that the acceptability of necessary truths was demonstrated by the self-contradictory character of their logical opposites. Mill held a somewhat more complex view of the epistemic status of natural laws.

Pause to reflect. The world could, for all we know, be very different. There is a clear case for concluding that any generalization over items of experience is contingent; it might, again for all we know, be false. More seriously, all known regularities could be replaced, in accordance with a plan or a successful wager on random possibilities. Such logical possibilities led some to propose that natural laws are endowed with a somewhat attenuated epistemic status.

Mill insisted that natural laws are inductively adequate descriptions of observed empirical regularities. Karl Pearson refined this idea: scientific laws, unlike civil laws which are prescriptive, are descriptive. They are valid for all normal human beings, not just for special communities at special times, and are ‘ unchangeable so long as their perceptive faculties remain at the same stage of development’ (1911). A natural law is not descriptive of repeated sequences of events existing outside us, but is what Pearson calls a ‘mental formula’. This initially perplexing idea had been given fuller treatment by several earlier nineteenth-century philosophers of science; surprisingly, Mill is one of them.

Although Mill thought that a scientific law can be understood as part of our knowledge of nature, he also thought that a law can be taken to be a ‘memorandum for our guidance’. As knowledge of nature, a law ‘registers’ facts; as a memorandum, it can be used as a guide to inference. Mill wrote: ‘ General propositions are merely registers of such [inductive] inferences already made, and short formulae for making more’ (1843). We do not draw inferences

from generalizations, but *in accordance with* generalizations taken as licensing certain inferences. We arrive at generalizations by collecting resembling particulars. No one of these particulars is specially privileged, and when we conclude that 'all particulars of sort *x* are particulars of sort *y*', and then go on to infer that some specific *x* is a *y*, we are, says Mill, 'merely deciphering our own notes'.

In commenting upon the generally accepted characterization of a law as a description, Mach prefers the term 'restriction on expectations' to point to the biological significance of scientific laws: ' in origin, the "laws of nature" are restrictions that under the guidance of our experience we prescribe to our expectations' ([1905] 1976). More fully:

> A law always consists in a restriction of possibilities, whether as a bar on action, as an invariable course of natural events, or as a road sign for our thoughts and ideas that anticipate events by running ahead of them in a complementary manner. Galileo and Kepler imagine the various possibilities of free fall and planetary motion, trying to guess those that correspond to observation and making them more precise. The law of inertia which assigns uniform rectilinear motion to a body once all forces disappear, selects one of infinitely many possible thoughts as the decisive one for our ideas.
>
> (Mach 1976: 352)

Mach is not denying that laws pick out observed invariable regularities. But human knowers are biological beings whose expectations are motivated by the need for preservation; laws of nature are instruments of orientation, rules of preservation. It is true that the refinement of laws requires abstraction from given experiences, simplification, idealization of facts and mental decomposition of facts into more cognitively manageable units, which allow us to deal with facts more efficiently (see Idealizations). Uniform and uniformly accelerated motions of masses, stationary (steady) thermal and electric currents, are examples of such idealized factual simples; as creatures of mind, they never occur in reality. 'Natural science may be viewed as a kind of collection of instruments for the intellectual completion of any partially given facts or for the restriction, as far as may be, of expectations in future cases'. This is one formulation of Mach's famous thesis of the economy of thought.

The instrumentalism of laws argued for by Mill, Pearson and Mach appears entirely consistent with the pragmatic positivism of the time. Instrumentalism is anti-metaphysical - in Mach and Mill it is even anti-theoretical. In stressing the specific human purposes that are to be fulfilled by seeking and employing laws, our three philosophers of science join forces with other nineteenth-century thinkers, who, like Herbert Spencer and Thomas Huxley, provide related arguments on behalf of the thesis that man is a progressive being.

It can be argued that instrumentalism is incoherent because it really cannot state its own case. Were there no ways in which nature invariably worked before the idealizing techniques of science came into play? Yes and no, answers the instrumentalist. Yes (perhaps), but who, as human knower, cares? No, because laws can only be useful for human knowers; laws restrict what we can know and do. Instrumentalism becomes a matter of perspective; it is a manner of viewing the efficacy of known natural law. But the perspective, though it provides orientation and patterns of adaptation, also displays limitations on what we can know if what we can know is truly only what we can successfully use. The laws, in addition, must be construed as mind-dependent, possible only because of the imposition and manipulation of ideas.

4 The logic of induction

The characteristics of inductive inference (as learning from experience) were much discussed by nineteenth-century philosophers of science. Whewell and Mill debated the question of just what constituted proper induction; Herschel provided the first rules of inductive procedure since Francis Bacon; Mach argued that conclusions of inductive arguments are as vacuous as those of deductive arguments; Mach, Pearson and Ernst Friedrich Apelt stressed the role of abstraction in scientific enquiry; James Clerk Maxwell championed a complex anti-theoretical methodology based on reasoning from analogies.

The core consideration here is the unwavering confidence of some philosophers of science in what they regarded as the logic of induction, a confidence emphatically proclaimed in Mill's statement that 'there are… certain and universal inductions; and it is because there are such, that a Logic of Induction is possible'. Herschel's nine 'general rules' were intended to provide guidance in the search for natural laws (or common causes of similar

phenomena), by permitting deliberate experimental manipulation of data in order to disclose the causes or laws. The suggestion is that, properly applied, the rules will generate valid inductive inferences.

Mill appropriates Herschel's rules in his simplified and generalized 'canons of induction', now better known as 'Mill's methods'. Induction, which for Mill is always inference from particular to particular, is based on consideration of sets of data constructed out of empirically noted regularities and similarities. Factors in a set are varied so that agreements and differences are detectable. These features may refer to invariable antecedence or consequence of certain factors, increase or diminution of certain factors, discovered proportionality of certain factors, and the like. In cases of valid inference, the causal analysis of varying factors will lead to discovery of a true cause, or a law of nature.

Mill thus follows one lead from the insightful writings of Herschel on scientific method. Whewell follows another. Herschel's rules and Mill's methods deal with what we might call 'local induction', generalization over known cases, and inference to others of the same kind not now known. Here, the only evidence that an induction is valid is that it covers the known cases, that it is empirically adequate. It had been recognized since the work of David Hume that any inferences beyond the known cases to all cases of the same (and sometimes different) kind (of global inductions), are hazardous at best, logically unwarranted at worst. Herschel suggests a test of such inferences that Whewell makes the cornerstone of his theory of method. Herschel writes:

> The surest and best characteristic of a well-founded and extensive induction… is when verifications of it spring up, as it were, spontaneously, into notice, from quarters where they might be least expected, or even among instances of that very kind which were at first considered hostile to them. Evidence of this kind is irresistible, and compels assent with a weight which scarcely any other possesses.
>
> (1830: 170)

Whewell calls this epistemic phenomenon a 'consilience of inductions', and regards the test as one capable of establishing the validity of some inductive inferences:

> The instances in which [consilience] has occurred, indeed, impress us with a conviction that the truth of our hypothesis is certain. No accident could give rise to such an extraordinary coincidence. No false supposition could, after being adjusted to one class of phenomena, exactly represent a different class, where the agreement was unforeseen and uncontemplated. That rules springing from remote and unconnected quarters should thus leap to the same point, can only arise from *that* being the point where truth resides.
>
> (1858a: 88)

Whewell regarded hypotheses (he called them 'colligations') as initiated by a mental act: the imposition of an idea on some body of data.Mach complimented Whewell on what Mach mistakenly thought was Whewell's concession to the role of freely fantasized and intuited hypotheses. But Whewell was more cautious. There are at least two kinds of restraint imposed on the selection of colligating ideas: success in the past employment of similar ideas, and fruitful discussions in the peer group of relevant scientists. Thus constrained, the idea used is to 'save the appearances', to provide a useful conduit to predictions of phenomena of the same kind as are in the original body of data. Successful prediction is thus one evidential test of a hypothesis, but it still operates on the local level, serving only to enlarge the items in the original set of data. Mill argued that successful prediction is of no evidential value; it only provides more items falling under the same description.

Whewell, the arch scientific realist, finally staked everything on global inductions, those successfully colligating *and* consiliating a hypothesis, adequately covering initial data, predictions of data of the same kind, and unexpected data originally thought to be different in kind, but now seen to be data of the same kind as items in the initial set. Recall Newton's hypothesis of universal gravitation, which covers motions of earthly bodies and of heavenly bodies, and the motions of the tides. Mill thought all induction was local induction, induction by enumeration. Although he agreed with Whewell that induction arrives at necessary truths, his comment on the value of consilience was deliberate silence.

A well-recognized feature of deduction is that deductive conclusions from premises convey no new information that is not contained in the premises but merely*analyse* the premises. The test of a valid deductive inference is that one should not be able to deny the conclusion, given the premises, without logical contradiction. It had also been a

long-standing view that inductive inferences yield conclusions that convey new information. It was generally thought that induction moves from the known to the unknown. Valid induction is discovery. The problem, underscored by the devastating analysis of causality by Hume, is to understand the respect in which induction can, like deduction, have a logic, for the conclusions of inductive inferences (as generalizations about the world) seem to involve contingent claims. Alternative conclusions are always *logically* possible.

Mach argued that inductive inference, like deductive inference, yields only vacuous conclusions. If it is simply a matter of piling up more and more instances, as in Mill's favoured induction by simple enumeration, then nothing really new is ever learned that could count as a law. All that one learns is that some data sets are larger than others. Mach's objection may apply to local induction of Mill's sort, but what about global induction? Here also Mach thinks no new information is obtained, for although in consilience data of an apparently new kind are involved, the consilience itself shows that they are not really different in kind from the initial data. If consilience really happens, it converts new data to old, and only extends the magnitude of the enumeration.

William Stanley Jevons delivers what looks like a fatal blow to any claim to have a logic of induction. Granting that science yields only approximations of the given in experience, involving as it does those factors stressed by Mach and Whewell - abstraction, simplification, idealization - any perfect fit between theory and observation must be grounds for suspicion that we are wrong, not for confidence that we are right. In the consideration of rival hypotheses, which are always possible in science, Jevons introduced subjectivist probability theory.

How, then, did believers in the possibility of a logic of induction justify induction?

5 The justification of induction

Herschel thought that the risk of error involved in Jevons's challenge is infinitesimal when we are dealing with ' the unbroken experience of all observers, in innumerable instances'. A conclusion from induction can 'enjoy [no] more than a provisional security'. Such a small risk should produce at least a practical, as distinct from a mathematical, certainty, 'in all physical inquiry, and in all transactions of life' (1857b). This pragmatic appeal to limited certainty would satisfy Mach, whose views on science as providing instruments for orientation have been discussed above. It would also satisfy Karl Pearson, and the biologically oriented Herbert Spencer. It would not, however, satisfy Mill or Whewell.

Whewell, the scientific realist, believed that science does establish laws that are universal truths, that contingent claims become necessary ones. The warrant for this belief is partly pragmatic: Whewell does appeal to the success of certain kinds of methodological technique as disclosed by the history of the inductive sciences. He also seeks a metaphysical justification of his scientific realism.

The historical record of attempts to justify induction reveals that for the most part philosophers rested content with an appeal to the principle of the uniformity of nature. Why trust induction? Inductive conclusions are based on invariable sequences of events. Why take them to be invariable? Nature is uniform. But the argument is viciously circular. We can only know that nature is uniform because we observe lots of sequences taken to be invariable. Or the argument appeals to metaphysical knowledge: nature is uniform because God made it that way. Or, as Herschel thought, the principle of uniformity is 'an axiom drawn from the inward consciousness of our nature, by involuntary generalization. We acknowledge it expressly or impliedly in every instant of life'.

Mill accepts a form of this argument as his justification of induction. We discover what we take to be laws of nature, invariable repeated sequences of events. What is the simplest assumption that can guarantee that we are right in our assumption that we have in fact discovered laws of nature? The assumption that there are laws of nature (that nature is uniform). This argument is not circular. It asks for the simplest assumption from which all of the known laws of nature can be deduced. The assumption is not inductively established, it is posited. Perhaps it is the best we can hope for (see Induction, epistemic issues in).

6 'The ultimate problem of all philosophy'

Whewell admitted with characteristic candour that what he called 'the ultimate problem of all philosophy' is profound, and probably unsolvable. This did not stop him from offering a solution. The problem is as old as scepticism: by means of human mental resources, we arrive at what we take to be knowledge of causal

connections, of natural necessity, how can we be sure that what we frame in mind exists in reality outside us? Whewell's committed Christianity provided him with the motivation that ensured a solution. The orders of human knowing correspond to real orders because God makes it so. Scientists share God's thoughts when they hit upon natural laws. That those laws involve independent realities is thus assured, since what God thinks, in these cases at least, he enacts.

Whewell's realism thus shifted its troubled burden on to a metaphysics as old as Leibniz's. He carries that burden alone. For Helmholtz, Hertz, Emil DuBois-Reymond and others, mechanism, the view that all natural phenomena conform to the fundamental principles of mechanics, provides the answer. Although there is no qualitative similarity between our sensations and ideas and their causes in the external world, there are the activities of nerve impulses, which mediate between the two. Physiology, as a part of physics, provides the argument for this reductionist position. Our ideas do not directly correspond to external realities, but both these realities and our ideas are, ultimately, to be viewed as the motions of atomic parts over distances.

We know that Mach was strongly opposed to the mechanical philosophy. He was also strongly opposed to considering Whewell's ultimate problem as a genuine one. Taking his cue from biology, he argued for the thesis that science provides human orientation in a complex world, not metaphysical guidance. Science aids us in our efforts to get along in this world, helps us to realize purposes. But there can be no question of identifying the economies of our successful ideas with an established pattern existing independently of us and holding for all time.

Herbert Spencer's similar biological interests led him to hold a view not unlike that of Mach. It may be true that the order of human knowing reflects accurately and without obdurate distortions the order of reality independent of the human mind, but this is because human beings evolve in the direction of better intellectual adaptation; any correlation between experience and law is not fixed. In the biological domain all change is towards equilibrium; this includes changes in knowledge as well as changes in social contexts.

The ultimate problem is basically the problem of scepticism: how can I trust that I know anything at all? Whewell leaves us in perplexity. There are those who will believe that the avenue to God's mind is forever closed for repairs. The same persons will likely also accept that those who coupled pragmatism and biology created, not an avenue, but a naturalistic horizon whose philosophical enticements constitute one of the benefits of later philosophy of science.

Science, philosophy of

1 Historical background and introduction

Science grew out of philosophy; and, even after recognizable, if flexible, interdisciplinary boundaries developed, the most fruitful philosophical investigations have often been made in close connection with science and scientific advance. The major modern innovators - Bacon, Descartes, Leibniz and Locke among them - were all centrally influenced by, and in some cases significantly contributed to, the science of their day. Kant's fundamental epistemological problem was generated by the success of science: we have obtained certain knowledge, both in mathematics and - principally due to Newton - in science, how was this possible? Unsurprisingly, many thinkers who are principally regarded as great scientists, had exciting and insightful views on the aims of science and the methods of obtaining scientific knowledge. One can only wonder why the epistemological views of Galileo and of Newton, for example, are not taught along with those of Bacon and Locke, say, in courses on the history of modern philosophy. Certainly it can be argued very convincingly that the former two had at least as much insight into the aims and methods of science, and into how scientific knowledge is gained and accredited as the latter two (see Galilei, G. §3; Newton, I. §§2-3; also see Boyle, R.; Copernicus, N.; Kepler, J.).

In the nineteenth century, Maxwell, Hertz and Helmholz all had interesting views about explanation and the foundations of science, while Poincaré who was undoubtedly one of the greatest mathematicians and mathematical physicists, was arguably also one of the greatest philosophers of science - developing important and influential views about, amongst other things, the nature of theories and hypotheses, explanation, and the role of probability theory both within science and as an account of scientific reasoning (also see Duhem, P.M.M.; French philosophy of science; Le Roy, É.; Meyerson, É.; Science, 19th century philosophy of).

The period from the 1920s to 1950s is sometimes seen as involving a movement towards more formal issues to the exclusion of detailed concern with the scientific process itself (see Logical positivism). While this has been over-exaggerated - Carnap, Hempel, Popper and especially Reichenbach for example all show sophisticated awareness of a range of issues from contemporary science (also see Bridgman, P.W.; Operationalism) - there is no doubt that general attention in philosophy of science has been redirected back to the details of science, and in particular of its *historical* development, by 'post-positivist' philosophers such as Hanson, Feyerabend, Kuhn, Lakatos and others.

Current philosophy of science has developed this great tradition, addressing many of the now standard philosophical issues - about knowledge, the nature of reality, determinism and indeterminism and so on - but by paying very close attention to science both as an exemplar of knowledge and as a source of (likely) information about the world. This means that there is inevitably much overlap with other areas of philosophy - notably epistemology (the theory of scientific knowledge is of course a central concern of philosophy of science) and metaphysics (which philosophers of science often shun as an attempted a priori discipline but welcome when it is approached as an investigation of what current scientific theories and practices seem to be telling us about the likely structure of the universe). Indeed one way of usefully dividing up the subject would see scientific epistemology and what might be called scientific metaphysics as two of the main branches of the subject (these two together in turn forming what might be called general philosophy of science), with the third branch consisting of more detailed, specific investigations into foundational issues concerned with particular scientific fields or particular scientific theories (especial, though by no means exclusive, attention having been paid of late to foundational and interpretative issues in quantum theory and the Darwinian theory of evolution). Again not surprisingly, important contributions have been made in this third sub-field by scientists themselves who have reflected carefully and challengingly on their own work and its foundations (see Bohr, N.; Darwin, C.R.; Einstein, A.; Heisenberg, W.; Planck, M.), as well as by those who are more usually considered philosophers.

2 Contemporary philosophy of science: the theory of scientific knowledge

Scientists propose theories and assess those theories in the light of observational and experimental evidence; what distinguishes science is the careful and systematic way in which its claims are based on evidence (see Scientific method). These simple claims, which I suppose would win fairly universal agreement, hide any number of

complex issues.

First, concerning theories: how exactly are these best represented? Is Newton's theory of gravitation, or the neo-Darwinian theory of evolution, or the general theory of relativity, best represented - as logical empiricists such as Carnap supposed - as sets of (at least potentially) formally axiomatized sentences, linked to their observational bases by some sort of correspondence rules? Or are they best represented, as various recent 'semantic theorists' have argued, as sets of models (see Models; Theories, scientific)? Is this simply a representational matter or does the difference between the two sorts of approach matter scientifically and philosophically? This issue ties in with the increasingly recognized role of idealizations in science and of the role of models as intermediates between fundamental theory and empirical laws (see Campbell, N.R.; Idealizations). It also relates to an important issue about how best to think of the state of a scientific field at a given time: is a scientist best thought of as accepting (in some sense or other) a single theory or set of such theories or rather as accepting some sort of more general and hierarchically-organized set of assumptions and techniques in the manner of Kuhnian paradigms or Lakatosian research programmes? It seems likely that arriving at the correct account of scientific development and in particular of theory-change in science will depend on identifying the 'right' account of theories.

Next concerning the *evidence*: it has long been recognized that many of the statements that scientists are happy to regard as 'observation sentences' in fact presuppose a certain amount of theory, and that *all* observation sentences, short perhaps of purely subjective reports of current introspection, depend on some sort of minimal theory (even 'the needle points to around 5 on the scale' presupposes that the needle and the scale exist independently of the observer and that the observer's perception of them is not systematically deluded by a Cartesian demon). Does this mean that there is no real epistemic distinction between observational and theoretical claims? Does it mean that there is no secure basis or foundation for science in the form of observational and experimental results (see Observation)? If so, what becomes of the whole empiricist idea of basing scientific theories on the evidence? It can be argued that those who have drawn dire consequences from these considerations have confused fallibility with (serious) corrigibility: that there are observation statements, such as reports of meter readings and the like, of a sufficiently low level as to be, once independently and intersubjectively verified, not seriously corrigible despite being trivially strictly fallible (see Measurement, theory of). Aside from this issue, experiment was for a long time regarded as raising barely any independent, philosophical or methodological concern - experiments being thought of as very largely simply means for testing theories (see Experiment). More recently, there has been better appreciation of the extent to which experimental science has a life of its own, independent of fundamental theory, and of the extent to which philosophical issues concerning testing, realism, underdetermination and so on can be illuminated by studying experiments.

Suppose that we have characterized scientific theories and drawn a line between theoretical and observational statements, what exactly is involved in 'basing' theoretical claims 'systematically and carefully' on the evidence? This question has of course been perhaps *the* central question of general philosophy of science in this century. We have known at least since David Hume that the answer cannot be that the correct theories are *deducible* from observation results. Indeed not only do our theories universally generalize the (inevitably finite) data as Hume pointed out, they also generally 'transcend' the data by explaining that data in terms of underlying, but non-observable, theoretical entities. This means that there must always in principle be (indefinitely) many theories that clash with one another at the theoretical level but yet entail all the same observational results (see Underdetermination). What extra factors then are involved over and beyond simply having the right observational consequences? What roles do such factors as simplicity (see Simplicity (in scientific theories)), and explanatory power (see Explanation), play in accrediting theories on the basis of evidence? Moreover what status do these factors have - are they purely pragmatic (the sorts of features *we* like theories to have) or are they truth-indicating, and if so why? Some have argued that the whole process can be codified in probabilistic terms - the theories that we see as accredited by the evidence being the ones that are at any rate *more probable* in the light of that evidence than any of their rivals (see Confirmation theory; Inductive inference; Probability theory and epistemology).

Finally, suppose we have characterized the correct scientific way of reasoning to theories from evidence, what exactly does this tell us about the theories that have been thus 'accredited' by the evidence? And what does it tell us about the entities - such as electrons, quarks, and the rest - apparently postulated by such theories? Is it reasonable to believe that these accredited theories are *true* descriptions of an underlying reality, that their theoretical terms refer to real, though unobservable entities? (Or at least to believe that they are *probably* true? or

approximately true? or perhaps probably approximately true?) More strongly still, is any one of these beliefs the *uniquely* rational one? Or is it instead more, or at least equally, reasonable - at least equally explanatory of the way that science operates - to hold that these ‘accredited’ theories are no more than empirically adequate, even that they are simply instruments for prediction, the theoretical ‘entities’ they involve being no more than convenient fictions (see Conventionalism; Fictionalism; Incommensurability; Putnam, H.; Scientific realism and antirealism)? One major problem faced by realists is to develop a plausible response to once accepted theories that are now rejected either by arguing that they were in some sense immature - not ‘fully scientific’ - or that, despite having been rejected, they nonetheless somehow live on as ‘limiting cases’ of current theories (see Alchemy; Chemistry, philosophical aspects of §2; Field theory, classical; Mechanics, Aristotelian; Mechanics, classical; Optics; Vitalism).

Clearly an antirealist view of theories would be indicated *if* it could convincingly be argued that the accreditation of theories in science is not simply a function of evidential and other truth-related factors or even of epistemic pragmatic factors, but *also* of broader cultural and social matters. Although such arguments are heard increasingly often, many remain unconvinced - seeing those arguments as based *either* on confusion of discovery with validational issues *or* on fairly naïve views of evidential support (see Constructivism; Discovery, logic of; Gender and science; Marxist philosophy of science).

3 Contemporary philosophy of science: ‘scientific metaphysics’

Suppose that we take a vaguely realist view of current science, what does it tell us about the general structure of reality? Does a sensible interpretation of science require the postulation, for example, of natural kinds (see Natural kinds) or universals? Does it require the postulation of a notion of physical necessity to distinguish natural laws from ‘mere’ regularities (see Laws, natural)? What is the nature of probability (see Probability, interpretations of) - is a probabilistic claim invariably an expression of (partial) ignorance or are there real, irreducible ‘objective chances’ in the world? What exactly is involved in the claim that a particular theory (or a particular system described by such a theory) is deterministic (see Determinism and indeterminism), and what would it mean for the world as a whole to be deterministic? Does even ‘deterministic’ science eschew the notion of *cause* (as Russell argued)? Does this notion come into its own in more ‘mundane’ contexts, involving what might be called ‘causal factors’ and probabilistic causation? What exactly is the relationship between causal claims - such as ‘smoking causes heart disease’ - and statistical data (see Causation)? How should spacetime be interpreted (see Spacetime): as substantive or as ‘merely’ relational? Does current science plus whatever ideas of causality are associated with it unambiguously rule out the possibility of time travel (see Time travel), or does this remain at least logically possible given current science?

Finally, and most generally, what is science (or, perhaps more significantly, the *direction* of scientific development) telling us about the overall structure of the universe - that it is one simple system governed at the fundamental level by one unified set of general laws, or rather that it is a ‘patchwork’ of interconnected but separate, mutually irreducible principles (see Unity of science; Reduction, problems of)? Although it is of course true - despite some exaggerated claims on behalf of ‘theories of everything’ - that science is very far from reducing everything to a common fundamental basis, and although it is of course true that, even in cases where reduction is generally agreed to have been achieved, such as that of chemistry to physics, the reduction is *ontological* (that is, chemistry has been shown to need no essential, non-physical primitive notions) rather than *epistemological* (no one would dream of trying actually to *derive* a full description of any chemical reaction from the principles of quantum mechanics), some would nonetheless still argue that the overall *tendency* of science is in the reductionist direction (see Chemistry, philosophical aspects of §5).

These are examples of the more or less general, and impressively varied, ‘metaphysical’ issues informed by science that have attracted recent philosophical attention.

4 Contemporary philosophy of science: foundational issues from current science

Many of the most interesting issues in current philosophy of science are closely tied to foundational or methodological concerns about current scientific theory. One fertile source of such concerns is quantum theory. How much of a revolutionary change in our general metaphysical view of the world does it require? Is the theory irreducibly indeterministic or do ‘hidden variable’ interpretations of some sort remain possible despite the negative

results? What does quantum mechanics tell us about the notion of cause? Does quantum mechanics imply a drastic breakdown of ‘locality’, telling us that the properties of even vastly spatially separated systems are fundamentally interconnected - so that we can no longer think of, for example ‘two’ spatially separated electrons as separate, independent ‘particles’? More directly, is there, in view of the ‘measurement problem’ a coherent interpretation of quantum mechanics at all? (It has been argued that when the theory is interpreted universally so that *all* systems, including ‘macroscopic’ ones, such as measuring apparatuses, are assigned a quantum state then the two fundamental principles of quantum theory - the Schrödinger equation and the projection postulate - come into direct contradiction (see Bell’s theorem; Field theory, quantum; Quantum measurement problem; Quantum mechanics, interpretation of; also see Randomness; Statistics).)

Although perhaps attracting relatively less attention than quantum theory, the other two great theories that form the triumvirate at the heart of contemporary physics - relativity (both special and general) and thermodynamics - pose similarly fascinating problems. In the case of relativity theory, philosophers have raised both ontological issues (for example, concerning the nature of spacetime) and epistemological issues (concerning for example the real role played in Einstein’s development of the theory by Machian empiricism, the role of allegedly crucial experiments such as that of Michelson and Morley (see Crucial experiments), and the evidential impact on the general theory of the Eddington star-shift experiment). There are also important issues about the consistency of relativity and quantum theory - issues that in turn feed into the more general questions concerning the unity of science and realism (see General relativity, philosophical responses to; Relativity theory, philosophical significance of).

Thermodynamics raises issues about, amongst other things, probability and the testing of probabilistic theories, about determinism and indeterminism, and about the direction of time (see Thermodynamics; Determinism and indeterminism; Duhem, P.M.M. §2; Time). Other current areas of physics, too, raise significant foundational issues (see Chaos theory, Cosmology).

For a long time, philosophy of science meant in effect philosophy of *physics*. A welcome broadening-out has occurred recently - especially in the direction of philosophy of biology. The central concern here has been with foundational issues in the Darwinian theory of evolution (or more accurately the neo-Darwinian synthesis of natural selection and genetics). Questions have been raised about the testability and, more generally, the empirical credentials of that theory, about the scope of the theory (in particular what it can tell us about humans and human societies), about the appropriate ‘unit of selection’ (individual, gene, group), about what exactly are genes and what exactly are species, and about whether evolutionary biology involves distinctive - perhaps even in *some* sense ‘teleological’ - modes of explanation (see Darwin, C.R.; Ecology; Evolution, theory of; Functional explanation; Genetics; Huxley, T.H.; Life, origin of; Linnaeus, C. von; Sociobiology; Species; Taxonomy; Wallace, A.R.). More recently philosophy of biology has started to widen its own scope by considering issues outside of evolutionary theory (see Molecular biology; Medicine, philosophy of), where, however, issues of reductionism and of the possibility of distinctive modes of explanation still loom large.

Scientific method

Procedures for attaining scientific knowledge are known as scientific methods. These methods include formulating theories and testing them against observation or experiment. Ancient and medieval thinkers called any systematic body of knowledge a 'science', and their methods were aimed at knowledge in general. According to the most common model for scientific knowledge, formulated by Aristotle, induction yields universal propositions from which all knowledge in a field can be deduced. This model was refined by medieval and early modern thinkers, and further developed in the nineteenth century by Whewell and Mill.

As Kuhn observed, idealized accounts of scientific method must be distinguished from descriptions of what scientists actually do. The methods of careful observation and experiment have been in use from antiquity, but became more widespread after the seventeenth century. Developments in instrument making, in mathematics and statistics, in terminology, and in communication technology have altered the methods and the results of science.

1 'Method' and 'science'

'Method' comes from the Greek *meta* (after) plus *hodos* (path or way). A method is a way to achieve an end; a scientific method is a way to achieve the ends of science. What those ends are depends on what science is or is taken to be. The word 'science' now means primarily natural science, examples of which are physics, astronomy, biology, chemistry, geology and psychology, and it applies secondarily to social sciences such as economics and sociology. Discussions of method focus on the cognitive aims of science, which may include knowledge, understanding, explanation, or predictive success, with respect to all or part of nature or to some domain of natural or social phenomena. Abstractly described, scientific method is the means for attaining these aims, especially by forming models, theories, or other cognitive structures and testing them through observation and experiment (see Experiment; Models; Observation; Theories, scientific). Investigations of scientific method may describe the methods actually employed by scientists, or they may formulate proposals about the procedures that should be followed to achieve scientific knowledge (see Naturalized philosophy of science).

The main features traditionally ascribed to 'the scientific method' - including clear statement of a problem, careful confrontation of theory with fact, open-mindedness, and (potential) public availability or replicability of evidence - are common to many cognitive endeavours, including much work in the humanities. Although there is no single method that distinguishes science from other intellectual practices, the following features are characteristic of the natural and social sciences: the use of quantitative data and of theories formulated mathematically; the use of artificially created experimental situations; and an interest in universal generalizations or laws (see Demarcation problem; Laws, natural §1; Unity of science). (But note that biological taxonomies are not intrinsically quantitative, and that neither astronomy nor economics is based primarily on experiment.) In both the natural and social sciences, the formation of models or theories may involve skills in mathematical computation and derivation, in evaluating consistency, in imagining new theoretical possibilities, in assessing the structure of a taxonomy, or in relating one area of investigation to other areas. The means for testing theories or generating new empirical knowledge vary widely, and include systematic observation, unsystematic observation, checks against background theories or knowledge, and various experimental procedures, including sophisticated statistical techniques, the construction of special instruments or apparatus and the use of specially bred laboratory animals.

2 Ideas of method from the Greeks to Thomas Kuhn

Because 'science' originally meant any systematic body of knowledge, ranging from mathematics to theology, the method of science was the method for obtaining, or perhaps merely for presenting and teaching, knowledge in general. Methods varied in relation to beliefs about what there is to be known.

The writings of Plato and Aristotle embody contrasting conceptions of both the objects of knowledge and the method for knowing them. In *Republic* VI, Plato divided the objects of knowledge into two realms: the visible and the intelligible (see Plato §14). He considered the former to include the objects of the senses, about which only opinion but not genuine knowledge is possible, and the latter to include geometry and astronomy, in which investigators assume the existence of their objects (such as geometrical objects) and reason from them as from hypotheses. In the highest reaches of the intelligible realm, reason attempts to reach 'the first principle of all that

exists', from which it then 'comes down to a conclusion…proceeding by means of Forms and through Forms to its conclusions which are Forms', without any reference to the visible world. Plato conceived the sensible world as a dim reflection of the intelligible Forms, and he held that the Forms themselves are best known through direct intellectual contemplation, independent of sensory experience. The notion of an intelligible world behind the sensible world, and especially of a world described by mathematics, has played an important role in physical science since Plato's time.

Aristotle rejected Plato's intelligible realm because it removed the objects of mathematical sciences such as astronomy from the sensible world, where he believed the forms of things are to be found. He carried out extensive observations (including dissections) in biology and developed a preliminary taxonomic scheme. Aristotle's principal discussion of method is the *Posterior Analytics*, a founding work in the philosophy of science. He accepted the Platonic distinction between a direction of cognition that is going 'to the forms' and the direction of cognition (as in syllogistic demonstration) that proceeds 'from the forms', but he conceived these processes as starting from sensible objects and arriving at knowledge of the common natures or essences of things as existing in those objects. Such knowledge (for instance, of the essence of a specific kind of mineral, or kind of living thing) yields a set of core propositions in each science, from which other knowledge is to be deductively derived.

Medieval philosophers, including Roger Bacon, John Duns Scotus and William of Ockham, commented extensively on Aristotle's methodological writings, which were later discussed at the University of Padua together with those of Galen. A central topic was the distinction between analysis and synthesis, or, as it was sometimes called, between resolution and composition. In the analytic phase of inquiry, one resolves the object of investigation into its basic constituents or least elements so as to determine its first principles. In the synthetic phase, one explains a subject matter from its first principles, or presents a body of knowledge by deriving it from such principles. In a common example, the analytic phase would include the search for the axioms, postulates and definitions of geometry; the synthetic phase the demonstration of theorems from those axioms and postulates. Bacon suggested that the first principles achieved in the analytic or inductive phase can be tested by deducing and checking new consequences (a feature of 'hypothetico-deductive' tests of theories). Scotus outlined a method of agreement, in which a possible cause for an effect is found by listing the circumstances that co-occur with the effect and looking for one that is present every time. Ockham suggested a method of difference, in which a circumstance that is present when the effect is present and absent when it is absent is considered as a possible cause for the effect.

The seventeenth century, a time of fundamental change in physics and astronomy, saw continuing attention to method within the inductive-deductive framework established by Aristotle. Francis Bacon outlined inductive procedures in detail, calling for extensive collections of data (named 'histories') which are to be culled systematically for general principles or laws. Galileo urged that mathematical descriptions be fitted to natural phenomena through observation and experiment (see Galilei, G.). Descartes wrote in *Discourse on the Method* (1637) that the derivation of an effect from a cause may serve as an explanation of the effect, and also as an empirical 'proof' of the posited cause (see Descartes, R. §6). Newton, in *Mathematical Principles of Natural Philosophy* (1729), laid down several 'hypotheses' or 'rules' for reasoning in natural philosophy. He advised investigators to avoid multiplying causes in relation to effects, to generalize from properties found in bodies that have been observed to all bodies in the universe, and to accept inductively supported propositions as 'accurately or very nearly true' until new observations improve upon their accuracy or limit their scope (see Newton, I. §4).

During the nineteenth century, the 'philosophy of science' or the 'logic of science' became, in the writings of William Whewell, John Stuart Mill and others, a main staple of philosophy (see Philosophy of science in the nineteenth century). Whewell's *Philosophy of the Inductive Sciences* (1840) analyses scientific knowledge of 'external' nature (excluding the mind itself). Whewell held that scientific knowledge is based upon sensations and ideas, the former being the 'objective' element (caused by objects), the latter a 'subjective' element (provided by the knowing subject). Consciously entertained facts and theories correspond to sensations and ideas, but not completely, because all facts implicitly include ideas (and so, possibly, theory). Whewell divided the methods of science into methods of observation, of obtaining clear ideas, and of induction. The methods of observation include quantitative observation (as in chemistry or astronomy) and the perception of similarities (as in natural history); observation includes both the collection and classification of facts. Clear ideas result from intellectual education (including both the mathematical sciences and natural history), and from discussion, including

(sometimes metaphysical) discussions of definitions, such as whether uniform force acting in free fall should be defined relative to space or to time. Science proceeds by ‘induction’, including the use of quantitative techniques to smooth out the irregularities of observation (that is, the ‘method of curves’ by which a curve is fitted to data points, the ‘method of means’ and the ‘method of least squares’) and the formation and empirical testing of tentative hypotheses. Laws of phenomena are usually formed first, but theories of true causes are desired, such as (Whewell explained) have been found in physical astronomy, physical optics, and geology, and might be found with respect to heat, magnetism, electricity, chemical compounds and living organisms.

In *A System of Logic* (1843), Mill analysed the methods of science even more fully than had Whewell, now including psychology and the social sciences (also known as the ‘mental’ and ‘moral’ sciences). In his analysis of experimental method, Mill included the methods of agreement and difference already mentioned, and added the method of residues, which directs the investigator to look for the (as yet unknown) causes of those effects that remain after all other effects have been assigned to known causes, and the method of concomitant variations, according to which those phenomena that vary regularly in quantitative degree with one another are assumed to be causally related. Like Whewell, Mill emphasized the role of new or pre-existing concepts and names in scientific observation, and the role that classification plays in induction. He proposed that psychology and the social sciences should adopt the explanatory structures of the natural sciences, a proposal frequently criticized since his time, notably by the Neo-Kantians Wilhelm Dilthey, Heinrich Rickert and Ernst Cassirer, who discussed methods pertaining to the ‘social’ or ‘human’ sciences, and who included the humanities as a form of ‘science’ (in German, *Wissenschaft*) (see Neo-Kantianism; Positivism in the social sciences).

Philosophers in the first half of the twentieth century, especially the Vienna Circle and Karl Popper, sought to analyse science and to reconstruct scientific reasoning using the new symbolic logic or the new theory of probability (see Vienna Circle). They continued the investigation of theory confirmation, focusing on recent theories in physics (see Confirmation theory). Rudolph Carnap attempted unsuccessfully to develop a quantitative theory of inductive support. Carl Hempel, who favoured a hypothetico-deductive account of scientific confirmation (involving the testing of theories by their deductive consequences), revealed certain paradoxes that result when the relation between scientific generalizations and confirming instances are expressed in predicate logic and certain (plausible) assumptions are made. Popper concluded that the defining feature of the empirical methods of science is that statements are always subjected to falsification by new data.

In the second half of the twentieth century philosophical analyses of scientific method broadened to again include sciences such as biology and geology, and paid greater attention to the history of science. N.R. Hanson recalled the often implicit role of theory in observation, questioning the notion of a theory-neutral observation language (see Observation §4). Thomas S. Kuhn emphasized the social nature of scientific communities and the common training that produces a shared vocabulary and set of experimental procedures. Kuhn and Paul Feyerabend stressed the need to distinguish the idealized accounts of scientific method given by some scientists and philosophers from the actual methodological practices of scientists. In studying the latter, historical and sociological investigation supplements the participatory acquaintance with scientific research possessed by scientists themselves and by some philosophers.

3 Scientific method in scientific practice

The methods of careful observation and description (including quantitative description) and of controlled experiment arose in antiquity and were practised by Greek, Hellenistic and Islamic investigators (see Philosophy of science in Islam §2). Examples include Aristotle’s biological observations, the many Greek and Arabic (and earlier Babylonian) tables of astronomical data, Ptolemy and Alhazen’s careful studies of binocular vision and distance perception, and Galen’s use of the ligature and other experimental techniques in physiology.

From antiquity, instruments aided the precision of observation in astronomy and optics. In the early seventeenth century Johannes Kepler used Tycho Brahe’s precise astronomical data (obtained with improved instruments) to establish the elliptical orbits of the planets and to determine the relations among the sizes and periods of those orbits. In 1609 Galileo used the newly invented telescope to observe previously unseen heavenly bodies (including the moons of Jupiter). Later in the century the microscope opened new fields of observation. The nineteenth and twentieth centuries have seen the development of refined and often complex instrumentation in all branches of natural science, including biology, chemistry and psychology, ranging from improved balances to the electron

microsope and the space telescope. Photography has been used to record data in nearly every field. The computer permits collection and manipulation of larger bodies of data than was previously practical. In psychology, the computer allows generation of precisely controlled stimuli and the recording of data with highly accurate temporal measurement.

The development of mathematics, including probability and statistics, has yielded new forms of theory statement and new descriptions of observational or experimental data. Mathematical sciences from antiquity to the seventeenth century used geometry almost exclusively. The development of algebraic geometry and of the calculus permitted new statements of Newtonian mechanics in the eighteenth century, and opened up new possibilities (theoretical as well as experimental) for describing and investigating functional relations among quantities. In the nineteenth and twentieth centuries, new mathematics has been demanded by or has facilitated mathematical physics. Thus, the discovery of non-Euclidean geometries opened up hitherto unforeseen theoretical possibilities in physical cosmology. The development of probability and statistics permitted the formulation of statistical laws, as in mathematical genetics, quantum physics and sociology (see Probability, interpretations of; Statistics; Statistics and social science). Inferential statistics is widely used in the analysis of quantitative data in psychology and other sciences.

Clear and precise terminology is an important feature of scientific methodology. Astronomy, optics (as the science of vision), natural history and medicine developed technical vocabularies in antiquity. Newton profoundly altered the terminology of physics, which continues to change as theories change. Carl von Linnaeus invented important taxonomies in botany and zoology; after Darwin’s theory of natural selection gained acceptance, evolutionary history influenced biological taxonomy (see Evolution, theory of; Taxonomy). Molecular biology has produced another new terminology (see Molecular biology). In psychology, long-standing mentalistic terminology was purged by twentieth-century behaviourists (see Behaviourism, methodological and scientific), and has since been reintroduced, partly under the influence of the computer metaphor for mental processes (see Mind, computational theories of). Likewise, economics, anthropology and sociology use refined technical vocabularies.

A sense of the various instruments and techniques of data collection and analysis now used can be gleaned from the materials, methods and results sections of scientific journals. Journals and other means of communication are themselves of methodological significance. The available methods for presenting observational data were radically altered by the development of printing (for both text and images), and again through computer-generated images and electronic communication. The mass production of standardized illustrations and printed data permits worldwide dissemination, utilization and hence testing of scientific findings.

The structure of scientific research groups and their interaction with scientific institutions, including the processes for deciding whether to fund research or to publish results, are also part of the method of science (broadly conceived). The methodological effectiveness of science can be evaluated at various scales, including the individual experiment, the individual investigator, the laboratory group, or the institutional structures by which collective instruments such as particle accelerators are administered. One might further examine the normative consequences of having relative homogeneity of methodological and theoretical belief across an active science, as opposed to the hedged bet of methodological and theoretical diversity. The student of scientific methods may investigate any aspect of the linguistic, conceptual, psychological, instrumental, social and institutional features of the sciences that affects their cognitive products.

Scientific realism and antirealism

Traditionally, scientific realism asserts that the objects of scientific knowledge exist independently of the minds or acts of scientists and that scientific theories are true of that objective (mind-independent) world. The reference to knowledge points to the dual character of scientific realism. On the one hand it is a metaphysical (specifically, an ontological) doctrine, claiming the independent existence of certain entities. On the other hand it is an epistemological doctrine asserting that we can know what individuals exist and that we can find out the truth of the theories or laws that govern them.

Opposed to scientific realism (hereafter just 'realism') are a variety of antirealisms, including phenomenalism and empiricism. Recently two others, instrumentalism and constructivism, have posed special challenges to realism. Instrumentalism regards the objects of knowledge pragmatically, as tools for various human purposes, and so takes reliability (or empirical adequacy) rather than truth as scientifically central. A version of this, fictionalism, contests the existence of many of the objects favoured by the realist and regards them as merely expedient means to useful ends. Constructivism maintains that scientific knowledge is socially constituted, that 'facts' are made by us. Thus it challenges the objectivity of knowledge, as the realist understands objectivity, and the independent existence that realism is after. Conventionalism, holding that the truths of science ultimately rest on man-made conventions, is allied to constructivism.

Realism and antirealism propose competing interpretations of science as a whole. They even differ over what requires explanation, with realism demanding that more be explained and antirealism less.

1 Arguing for realism

Late nineteenth- and early twentieth-century debates over the reality of molecules and atoms polarized the scientific community on the realism question. Antirealists like Mach, Duhem and Poincaré - representing (roughly) phenomenalist, instrumentalist and conventionalist positions - at first carried the day with a sceptical attitude towards the truth of scientific theories and the reality of the 'theoretical entities' employed by those theories (see Phenomenalism; Conventionalism). Led by the successes of statistical mechanics (see Thermodynamics) and relativity (see Relativity theory, philosophical significance of), however, Planck and Einstein helped turn the tide towards realism. That movement was checked by two developments. In physics the quantum theory of 1925-6 quickly ran into difficulties over the possibility of a realist interpretation (see Quantum mechanics, interpretation of) and the community settled on the instrumentalist programme promoted by Bohr and Heisenberg. This was a formative lesson for logical empiricism whose respect for developments in physics and whose positivistic orientation led it to brand the realism question as metaphysical, a pseudo-question (see Logical positivism, philosophy of). Thus for a while empiricist and instrumentalist trends in science and philosophy eclipsed scientific realism.

The situation changed again in the 1960s, by which time science and its technological applications had become a ubiquitous and dominant feature of Western culture. In this setting philosophers like Smart (1963) and Putnam (1975) proposed what came to be known as the 'miracles' argument for scientific realism (see Smart, J.J.C. §3; Putnam, H. §2). They argued that unless the theoretical entities employed by scientific theories actually existed and the theories themselves were at least approximately true of the world at large, the evident success of science (in terms of its applications and predictions) would surely be a miracle. It is easy to see, at least with hindsight, that the most one could conclude from scientific success, however impressive, is that science is on the right track. That could mean, as the argument concludes, on the track to truth or it could just mean on the track to empirical success, perhaps with deeply flawed representations of reality. The 'miracles' argument is inconclusive. Nevertheless, during the next two decades it was compelling for many philosophers. Indeed, during this period realism became so identified with science that questioning realism was quickly put down as anti-science.

Realist orthodoxy found support in Popper's attack on instrumentalism, which he criticized as unable to account for his own falsificationist methodology (Popper 1956) (see Popper, K.R. §2). Broadening this line, Boyd developed an explanationist version of the 'miracles' argument that focused on the methods of science and tried as well to give proper due to the human-centred (constructivist and conventionalist) aspects of science emphasized by Kuhn and Feyerabend. Boyd asks why methods crafted by us and reflecting our interests and limitations lead to

instrumentally successful science. Contrasting realism with empiricism and constructivism, he finds that realism offers the best (indeed, the only) explanation. That is because, he argues, if we begin with truths or near-truths the methods we have crafted for science produce even more of the same. Since it is only realism that demands the truth of our scientific theories, then realism wins as giving the best explanation for the instrumental success of science. Hence, like a scientific hypothesis, realism is most likely to be true and we should believe in it.

The explanationist argument is carefully framed so that we ask only about the instrumental success of science; that is, success at the observational level. To take science as successful (for example, truth-producing) at the theoretical level would beg the question against empiricism and instrumentalism. Once this is recognized, however, we can see a significant gap in the reasoning. The argument is driven by a picture of science as generating new truths from old truths, but the explanatory issue raised is only about truths at the level of observation, not about truths in general. Antirealists might well reject this as an illegitimate request for explanation. If they accept it, there is an obvious empiricist or instrumentalist response: namely, that our scientific methods are made by us to winnow out instrumentally reliable information. If we begin with fairly reliable statements, the methods we have crafted for science will produce even more. Thus the explanation for scientific success at the instrumental level need not involve the literal truth of our scientific principles or theories, just their instrumental reliability. This move nicely converts the argument for realism as the best explanation of scientific success into an argument for instrumentalism.

There is a second problem with the explanationist tactic, perhaps even more serious. The conclusion in support of realism depends on an inference to the best explanation (see Inference to the best explanation). That principle, to regard as true that which explains best, is a principle that antirealisms (especially instrumentalism and empiricism) deny. Van Fraassen, for example, regards being the best explanation as a virtue, but one separate from truth. (He reminds us that the best may well be the best of a bad lot.) Although not required, there could perhaps be an instrumentalist principle of inference to the best explanation. It would not infer to the truth of the explanation but to its instrumental reliability (or empirical adequacy) - precisely the strategy pursued above where we infer instrumentalism from the instrumental success of science. Thus the explanationist argument uses a specifically realist principle of inference to the best explanation and, in so doing, begs the question of truth versus reliability, one of the central questions at issue between realism and antirealism.

2 Piecemeal realisms

Inference to the best explanation promised the most cogent version of the ‘miracles’ argument. Its inadequacy hastened a retreat from realism’s original undertaking as a global interpretation of science. Retreat was fostered by two other antirealist developments. One was the pessimistic meta-induction to the instability of current science, a conclusion based on the repeated overthrow of scientific theories historically and the consequent dramatic alterations in ontology. The other was a sharpening of the underdetermination thesis associated with Poincaré and Duhem, suggesting that there may be empirically equivalent theories between which no evidence can decide (see Underdetermination). Both developments tended to undermine claims for the reality of the objects of scientific investigation and the truth of scientific theories.

Pursuing a salvage operation, several philosophers suggested that realism could confine itself to being a doctrine about the independent existence of theoretical entities (‘entity realism’) without commitment to the truth of the theories employing them. Hacking (1983) proposed an ‘experimental argument’ for this entity realism; roughly, that if you can deploy entities experimentally to discover new features of nature (for example, use an electron gun to learn about quarks), then the entities must be real whether or not the covering theories are true (see Experiment §3). Cartwright (1983) suggested that the strategy of inference to the best explanation be confined to an inference to the causes of phenomena, since causes are unquestionably real. To the antirealist, however, these related strategies seem far from compelling. For one thing, it is not clear that one can so neatly disengage theoretical entities from their covering theories. Moreover, in both cases, we can see that the basis on which one is asked to draw a realist conclusion need support no more than a conclusion about utility or reliability. In Hacking’s case one need conclude only that electrons are a useful theoretical construct (perhaps a useful fiction?) and in Cartwright’s that certain causal hypotheses are reliable in certain domains.

Faced with these difficulties realism has fragmented even further. Sometimes it takes an historicist turn, countering the pessimistic meta-induction by endorsing as real only those fruitful entities that survive scientific revolutions.

Sometimes realism becomes highly selective in other ways; for example, looking only at what seems essential in specific cases of explanatory or predictive success, or at entities that stand out as supported by only the very best scientific evidence. Although each of these principles locates matters of scientific significance, it is not clear that such criteria overcome the general strategies that have undone global realist arguments. In particular they do not seem to discriminate effectively between what is real and what is merely useful (and so between realism and instrumentalism).

3 Alternatives to realism

Several alternatives to realism have developed in the course of these debates. Principal among them are Putnam's 'internal realism' (1981) (see Putnam, H. §8), van Fraassen's 'constructive empiricism' (van Fraassen 1980) and what Fine (1986) calls 'the natural ontological attitude', or NOA. In a chameleon-like move, Putnam switched from being realism's champion to its critic. Rejecting what he called 'metaphysical realism' (associated with a 'God's eye view'), Putnam proposed a perspectival position in which truth is relative to language (or conceptual scheme). He could then allow scientific claims to be true in their proper domain but deny that they tell the whole story, or even that there is a whole story to tell. His picture was that there could be other truths - different stories about the world - each of which it may be proper to believe. Van Fraassen's constructive empiricism eschews belief in favour of what he calls commitment. He takes the distinguishing features of realism as twofold: realism seeks truth as a goal, and when a realist accepts a theory it is accepted as true. Constructive empiricism, by contrast, takes empirical adequacy (not truth) as the goal of science, and when it accepts a theory it accepts it as empirically adequate. This involves commitment to working within the framework of the theory but not to believing in its literal truth. Unlike these others, Fine's NOA is not a general interpretive scheme but simply an attitude that one can take to science. The attitude is minimal, deflationary and expressly local. It is critically positive, looking carefully at particular scientific claims and procedures, and cautions us not to attach any general interpretive agenda to science. Thus NOA rejects positing goals for science as a whole, as realists and constructive empiricists do. NOA accepts 'truth' as a semantic primitive, but rejects any general theories or interpretations of scientific truth, including the perspectivalism built into internal realism and the external-world correspondence built into realism itself. NOA is perhaps better classified as a nonrealism than as an antirealism.

It is interesting to contrast how these positions respond to good science. Realism accepts good science as true of an observer-independent world; internal realism accepts it as true relative to our scheme of things; constructive empiricism accepts it only as empirically adequate. NOA simply accepts it. This brings out two significant features of the recent debates. One is that they are more about the reach of evidence (what kind of acceptance is warranted) than about the metaphysical character of the objects of belief. The contrast also shows that major contenders, whether realist or not, share a basically positive attitude towards science. This has not always been acknowledged and a contrary suspicion still attaches to constructivism, which is frequently regarded as anti-science.

4 The constructivist challenge

Contemporary developments in the history and sociology of science have revived constructivist approaches (see Constructivism). Sharing with instrumentalism and other forms of pragmatism an emphasis on science as an activity, constructivism borrows the Marxist vocabulary of the 'production' of ideas (see Marxist philosophy of science) to place science among the manufacturing institutions. Specifically, what science makes is knowledge, which includes concepts and theories, along with things and even facts. Constructivism also emphasizes that science is open-ended. It highlights the role of unforced judgment in scientific practice, challenging the picture of a strict scientific method and of decision-making forced by rationality at every turn. The upshot is to see science as a form of human engagement like others; just people doing their own thing as best they can. Many regard this placement of science as a displacement, demoting science from its privileged position as the paradigm of rational and objective inquiry.

The emphasis on human constructions may challenge the mind-independence that is the hallmark of realist metaphysics. The respective roles of the social order and of nature in shaping these constructions, however, differ among constructivists, making for strong idealism at one pole (see Idealism) and pragmatic realism at the other. Despite these differences, constructivism challenges the unique position that realism marks out for itself with respect to ongoing science. If we look beyond the relatively sophisticated arguments for realism rehearsed above, perhaps realism's major hold on our attention is its claim to offer the only viable setting for understanding

scientific practice. We are told that unless we take scientists to be engaged in finding out about a world not of their own making we cannot begin to understand how science works. The major constructivist challenge is right here. The heart of constructivism consists in richly detailed studies of science in action. These studies set out to understand how science actually proceeds while bracketing the truth-claims of the area of science under investigation. Instead, constructivists typically employ little more than everyday psychology and an everyday pragmatism with respect to the common objects of experience. To the extent to which these studies succeed they paint a picture of science quite different from realism's, a constructivist picture that may undermine not only the arguments but also the intuitions on which scientific realism rests.

Scientific realism and social science

A central issue in the philosophy of the social sciences is the possibility of naturalism: whether disciplines such as sociology, anthropology, economics and psychology can be 'scientific' in broadly the same sense in which this term is applied to physics, chemistry, biology and so on. In the long history of debates about this issue, both naturalists and anti-naturalists have tended to accept a particular view of the natural sciences - the 'positivist' conception of science. But the challenges to this previously dominant position in the philosophy of science from around the 1960s made this shared assumption increasingly problematic. It was no longer clear what would be implied by the naturalist requirement that the social sciences should be modelled on the natural sciences. It also became necessary to reconsider the arguments previously employed by anti-naturalists, to see whether these held only on the assumption of a positivist conception of science. If so, a non-positivist naturalism might be defended: a methodological unity of the social and natural sciences based on some alternative to positivism. That this is possible has been argued by scientific realists in the social sciences, drawing on a particular alternative to positivism: the realist conception of science developed in the 1970s by Harré and others.

1 Realist v. positivist views of science

Within the philosophy of science, scientific realists criticize positivism both on philosophical grounds, and for failing adequately to represent the nature of scientific theories and their historical development. Rejecting the positivists' deductive-nomological model of explanation as unable to distinguish predictive from explanatory power, realists argue that scientific explanation consists in describing the processes through which observable phenomena, and whatever regularities obtain between them, are generated by the operation of (typically unobservable) underlying structures and mechanisms. In doing so, they likewise reject the regularity view of causation and defend a concept of natural necessity together with a Lockean view of causal powers.

This view of explanation brings with it a far less restrictive attitude towards the ontological commitments of scientific theories than positivism permits. For although (most) positivists accept what may be termed the 'minimal realist' claim that science aims at knowledge of an external world whose existence and nature are independent of the knowing subject (see Realism and antirealism), scientific realists criticize the positivists' tendency to limit what can be said to exist to what is observable, directly measurable, and so on. They therefore reject both operationalist and instrumentalist interpretations of the cognitive status of theoretical concepts, instead regarding them as having, at least potentially, a straightforwardly referential function (see Theories, scientific). Further, whereas for positivists, scientific progress is largely a matter of the increasing scope and hence predictive-explanatory power of universal laws, for scientific realists it consists primarily in increasing theoretical depth, with each level of causally operative structures and mechanisms being successively explained by reference to other, deeper levels. In such developments, existential hypotheses concerning previously unimagined entities - by contrast with the universal hypotheses emphasized by positivists - often play a central role.

Adopting this alternative to the positivist conception of science, realist naturalists have attempted both to articulate the character of a realist social science (§2), and to disarm a number of influential anti-naturalist arguments (§3).

2 The nature of a realist social science

Some realists, notably Bhaskar in *The Possibility of Naturalism* (1979), have seen it as their task to identify the ontological presuppositions of a realist social science, especially the nature of the agency-structure relationship (see Critical realism). But others, such as Keat and Urry in *Social Theory as Science* (1975), have pursued more modest aims: to free social science from the unnecessary and impoverishing limitations of positivism, and to indicate what kinds of theoretical work in the social sciences would be consistent with, or suggested by, their being modelled on a realist view of natural science.

Obvious examples of such positivistically inspired limitations are provided by the various forms of behaviourism in psychology and other social sciences (see Behaviourism, methodological and scientific). For realists, mentalistic concepts can be seen as performing a similar function to theoretical concepts in the natural sciences: potentially referring to unobservable entities, structures and processes, and employed in theories that can be tested for their explanatory power like any others. Hence there is no a priori reason either to eliminate them altogether, to provide

them with operational definitions in behavioural terms, or to regard them instrumentally, as no more than convenient fictions or predictive devices.

Nor, for the realist, need the realm of the mental be restricted to that of consciousness. Hence, whereas positivists have often regarded psychoanalytic theory as ‘unscientific’ or even ‘metaphysical’, realists may view Freud’s arguments for the postulation of ‘the unconscious’ as on a par with those typically adduced in postulating theoretical entities in the natural sciences, and his attempts to specify the nature of its structures and mechanisms as, in principle, a perfectly legitimate exercise in scientific theorizing.

However, none of this should be taken to imply that realists do or must endorse the substantive truth or explanatory power of mentalistic or psychoanalytic theories. A realist philosophy of the social sciences provides no more guidance about the truth or falsity of specific theoretical claims than does realism in the natural sciences. This applies equally to what has been, in the work of many realist naturalists, the main example of a substantive social theory open to a realist interpretation, namely Marx’s materialist theory of history and his attempts to identify the underlying structures of the various ‘modes of production’, such as capitalism and feudalism, and the nature of their respective generative mechanisms, such as their specific means of extracting surplus value.

Since Marxism, psychoanalytic theory and mentalistic psychology all seem to provide bona fide examples of the kinds of theoretical enterprise permitted by realism, its adoption should not be seen as implying commitment to a materialist ontology: not only material but also ideational items (such as beliefs, values and conceptual schemes) may legitimately be referred to by the theoretical concepts of a realist social science. Indeed realism would seem to be consistent even with ‘idealism’ in the social sciences, that is, with the claim that the social world is exclusively ideational in character: provided, of course, that these ideational items meet the minimal realist requirement of existing independently of the social scientist’s supposed knowledge or theoretical representation of them.

There is, however, a quite different sense of ‘idealism’, according to which the ‘objects of knowledge’ are themselves constructed or constituted by the knowing subject, and/or by the conceptual frameworks within which specific scientific theories are articulated (see Idealism). Idealism in this latter sense is clearly incompatible not just with scientific realism in the social sciences, but with any minimally realist view of either the social or natural sciences. These two senses of ‘idealism’ are often confused in debates about the social sciences: in particular, by some post-structuralist social theorists who adopt both forms of idealism without noticing their inconsistency in doing so.

3 Scientific realism and anti-naturalism

In its most general form, the anti-naturalist claim is that there is something about the character of the social world that makes it an impossible or inappropriate object of inquiry modelled upon the natural sciences. What realist naturalists try to show, in effect, is that this ‘something’, while excluded by a positivist social science, can find a suitable home in a realist one.

The most influential versions of anti-naturalism focus on the distinctively ‘meaningful’ character of social phenomena, and argue that these require, in place of scientific explanation, some form of ‘understanding’: the so-called ‘understanding *v.* explanation’ thesis. According to one version of this thesis, such understanding consists in identifying the reasons that people have for their actions, and/or in relating these to social rules of various kinds. To this the realist may respond by claiming that, once positivistic restrictions on theoretical entities are removed, there are no grounds for excluding such ‘meaningful’ items from the social sciences, nor for rejecting the possibility of causal relations obtaining between them. Thus such ‘understanding’ of actions can be seen as a form of causal explanation, with agents’ reasons as the mental causes (beliefs, desires and so on) of their behaviour. Correspondingly, the distinction between (physical) behaviour and (meaningful) action, much cited by anti-naturalists, may be interpreted by realists as one between observable phenomena and a theoretical redescription of these referring to their presumed causal determinants, something that is commonplace in the natural sciences.

But there are other versions of the understanding *v.* explanation thesis, especially those associated with the hermeneutic tradition, that are less obviously open to this naturalist rejoinder from a realist standpoint (see Hermeneutics). Here the concern is not with the nature of the relationship between reasons/rules and actions, but with the epistemological and methodological character of the ‘interpretive’ process through which the

identification of these reasons and rules itself takes place.

Consider, for example, the claim that agent A’s reason for action X is their belief that P, where P is some proposition. Even if, as the realist maintains, A’s believing that P can in principle be seen as (part of) the cause of their doing X, there remains the question of what exactly is involved in the identification of P itself. There is surely some process of ‘interpretation’ here, through which the meaning or content of this proposition is grasped or understood; and similarly for social rules and the like. Nor need this interpretive process stop at ‘surface’ meanings: one may also go further, through various ‘depth-hermeneutic’ procedures, to arrive at more fundamental levels of belief, meaning and so on.

Admittedly, there is also a necessary role for such interpretive processes in the conduct of the natural sciences, namely in the communicative interactions that take place between members of a scientific community. But there, it would seem, such interpretive procedures play no part in identifying or understanding the objects of scientific inquiry themselves. For these, unlike their counterparts in the social sciences, are essentially non-meaningful in character.

The scientific realist may respond to such claims by arguing that provided the structures of meaning arrived at in this way meet the minimal realist requirement of existing independently of the interpretive procedures employed - something that is accepted by some, though by no means all hermeneutic theorists - a qualified form of naturalism remains defensible. For the interpretation of meanings may then be seen, not as replacing the explanatory aims of a realist social theory, but rather as serving to identify the nature of the entities to which reference must be made in pursuing that explanatory project. Thus interpretation, while necessary given the distinctive nature of social phenomena, is not by itself enough: it must be combined with causal explanation of a recognizably ‘scientific’ kind.

However, this partial concession by the realist is unlikely to satisfy most anti-naturalists. Many would deny, for example, the possibility of objective hermeneutic interpretation, or would view with suspicion the realist’s attempt to assimilate the ‘unobservability’ of structures and mechanisms in nature and that of meanings in the social world. At this point, perhaps, what is required is a more nuanced and discriminating account of naturalism and anti-naturalism themselves, to make clear just what it is that the natural and social sciences are being asserted or denied to have in common.

Scope

Scope is a notion used by logicians and linguists in describing artificial and natural languages. It is best introduced in terms of the languages of formal logic. Consider a particular occurrence of an operator in a sentence - say, that of ' $\rightarrow$ ' in (1) below, or that of the universal quantifier ' $\forall$ ' in (2) below.

(1) $A \rightarrow (B \,\&\, C)$
(2) $\forall x(Bxy \rightarrow \exists yAxy)$

Speaking intuitively, the scope of the operator is that part of the sentence which it governs. The scope of ' $\rightarrow$ ' in (1) is the whole sentence; this renders the whole sentence a conditional. The scope of 'Čamp;', on the other hand, is just '(B & C)'. In (2), the scope of the quantifier ' $\forall$ ' is the whole sentence, which allows it to bind every occurrence of x. The scope of ' $\exists$ ' is only ' $\exists yAxy$ '. Since 'Bxy' is outside its scope, the 'y' in 'Bxy' is left unbound.

Although the importance of scope is semantic, it is usually identified with a syntactic relation between an occurrence of an expression in a sentence and a part of that sentence. In sentence and quantifier logic, the scope of an occurrence of an operator in a sentence *S* is usually defined as the smallest sub-sentence of *S* containing the occurrence. This ensures that for any two (occurrences of) operators with overlapping scope, exactly one is in the other's scope. In '$A \rightarrow (B \,\&\, C)$', for example, 'Čamp;' is in the scope of ' $\rightarrow$ ', and not vice versa. When the scope of one operator includes that of a second, the first is said to have wider scope than the second; the second's scope is narrower than that of the first.

Many semantically significant properties are characterized in terms of scope. The main logical operator of a sentence is the operator with the whole sentence as its scope. Thus conjunction, universal quantification, necessitation and so on are defined in terms of scope. A variable is bound whenever it occurs in the scope of a quantifier on it. A *de re* sentence is a sentence, such as ' $\exists x$ I believe that *x* is a spy', in which a variable in the scope of a non-extensional operator (like 'believes' or 'necessarily') is bound by a quantifier outside that operator's scope. *De dicto* sentences are ones which do not involve such 'quantifying in' (see De re/de dicto).

Differences in relative scope can affect a sentence's truth-conditions. 'Many hate a few' has an interpretation, in which 'many' gets wide scope, on which it says that many have the property 'hating a few'. It has a quite different reading in which 'a few' gets wide scope, on which it says that a few have the property 'being hated by many'. If the quantifier 'someone' in 'I believe that someone is a spy' has a narrower scope than 'believes', the sentence does not imply that there is some individual whom I think is a spy; if the quantifier's scope is wider, it does imply this.

In a well-designed formal language, the relative scope of operators is indicated by surface syntax, but this is not inevitably true in natural language. A natural language sentence with *n* operators has potentially *n*! (*n* factorial: $n(n-1)\ldots 3 \times 2 \times 1$) readings, since there are in principle that many ways of ordering the scopes of the operators. (Not all such orderings need be linguistically possible, of course.) Such ambiguities need to be resolved by an interpretive process, or a user's intentions, before the sentence can be evaluated for truth. Some syntactic theories posit a stage in sentence generation ('logical form') at which quantifier scope ambiguities are resolved by moving quantifiers so that their relative positions encode their scope (see Logical form).

A quantifier's scope should be the domain in which pronouns 'anaphoric on' (referring back to) the quantifier behave as variables bound by it. For example, the occurrence of 'her' in

(1) Every woman knew a man who loved her,

if anaphoric on 'every woman', behaves as a bound variable, since (1) is then understood as equivalent to

(1′) $\forall x(x$ is a woman $\rightarrow x$ knew a man who loved *x*),

and the scope of 'every woman' is therefore the whole sentence.

Observe that only some uses of pronouns anaphoric on quantifiers behave like variables bound by those

quantifiers. For example, consider the sentence

(2) Garth bought some dogs and Wayne vaccinated them.

Even when anaphoric on ‘some dogs’, ‘them’ in (2) cannot be treated as a bound variable. If it were a bound variable, then the sentence as a whole would be equivalent to

(3) There are some dogs Garth bought which Wayne vaccinated,

but (3) does not imply that Wayne vaccinated *all* the relevant dogs, as (2) does. (Gareth Evans (1985) seems to be the first person to have noticed this.) So ‘them’ is to be excluded from the scope of the quantifier ‘some dogs’. In accounts of natural language grammar which identify sentences with tree structures, quantifier scope is often identified with a structural relation between tree parts called c-command. While an expression in one sentence may be anaphoric on one in another, it is not possible for an expression in one sentence to c-command an expression in another. In particular, ‘some dogs’ in (2) does not c-command ‘them’. It follows, on such accounts, that not all pronouns anaphoric on a quantifier are bound thereby.

Russell (1910-13) speaks of the scope of a description in giving his ‘definition in use’ for (that is, method for eliminating) definite descriptions. When the scope of a description ‘the *F* in a sentence *S* is a sub-sentence ‘*T*(the *F*)’ of *S*, Russell says *S* is equivalent to the result of substituting (a formalization of) ‘there is exactly one *F*, and *T*(it)’ for ‘*T*(the *F*)’ in *S*. For example, if, in ‘Possibly, the mayor is mad’, the scope of the description is the whole sentence, the sentence is equivalent to ‘There is exactly one mayor and possibly it is mad’. If the scope of the description is just ‘The mayor is mad’, the sentence is equivalent to ‘Possibly: there is exactly one mayor and it is mad’. Russell’s account makes the definite article semantically analogous to a binary quantifier.

Expressions other than quantifiers and connectives also have scope. Variable binders (such as function abstractors) and verbs which take sentential complements (for example, ‘to believe’) are examples. Standard definitions extend straightforwardly here.

One hears it said that proper names ‘always take wide scope’. This seems intended as the claim that what is said by a use of a sentence *S*(*n*), with *n* a proper name, is what would have been said by an appropriately related use of a sentence of the form ‘*n* is such that *S*(it)’, with ‘it’ anaphoric on *n*.

Searle, John (1932-)

John Searle was a pupil of J.L. Austin at Oxford in the 1950s. He is the Mills Professor of Mind and Language at the University of California, Berkeley, where he has taught philosophy since 1959. According to Searle, the primary objects of analysis in the philosophy of language are not expressions but the production of expressions, speech acts, in accordance with rules. Learning a language involves (often unconsciously) internalizing rules that govern the performance of speech acts in that language. Speech-act theory aims to discover these rules and is itself a part of action theory, which concerns intentional states directed at or about something. It follows that speech-act theory is part of a more comprehensive theory of intentionality.

1 Speech acts and intentionality

Searle's career has primarily been devoted to developing a general theory of intentionality, beginning with *Speech Acts* (1969), moving deeper into his analysis in *Intentionality* (1983). Pursuit of questions about how words relate to the world crystallized for Searle questions about how the mind relates to the world. The conditions of satisfaction of speech acts derive from the conditions of satisfaction of corresponding psychological states. In *The Rediscovery of the Mind* (1992), Searle reaffirms his general picture. A theory of language is incomplete without an account of the relation between mind and language and of how meaning - the derived intentionality of linguistic elements - is grounded in the more biologically basic intrinsic intentionality of the mind/brain.

Searle's view that intentional states are related to a network of other intentional states, though not indisputable, is nevertheless in the mainstream. Commitment to the network is a form of holism; only relative to a vast range of other intentional states does any single intentional state have conditions of satisfaction. His view that intentional states function only against a background of skills is less widespread. These skills cannot be reduced to rules, nor can they be explicated by appeal to intentional states themselves, for they do not function as representations. But understanding literal meaning, and in particular, metaphor, requires this background. An oddity of the background is that, though the network fades off into it, the background itself is not intentional, but still involves some kind of stance towards the world (see Holism: mental and semantic).

Underlying Searle's general approach is the view that any divide between the mental and the physical is logical, not ontological, since in his view intentional states are caused by, and realized only in, physical structures. However, unlike mainstream philosophers of mind who worry how physical phenomena can have intentional properties, Searle since the late 1970s has been saying that the mind-body problem has a simple solution. Instead of this problem, Searle takes consciousness to be the central issue in the philosophy of mind. He has been successful in recruiting lots of others to refocus philosophical attention on consciousness (see Consciousness).

In *The Construction of Social Reality* (1995) Searle promotes his view about collective intentional behaviour. There is a difference between a group of people merely running around a field and a group playing football. According to Searle, this difference cannot be analysed as the sum of the behaviour of individuals. Since bodily movements can be (type-)identical in both cases, Searle infers that the difference lies in their minds. For those playing football, each has a collective intention of the form 'we intend to play football', distinct from, and irreducible to, individual intentions of the form 'I intend to run downfield twenty yards' or even 'I intend to play football'. Rejecting any suggestion that collective intentions are the product of a mysterious Hegelian communal mind, Searle incorporates collective intentions into his individualistic theory of intentionality. Since all mental phenomena are caused by operations of the brain and realized in its structure, there too must collective intentions lie.

2 Defending common sense

Though §1 sketches some of Searle's contributions to philosophy to date, it fails to reveal his greatest impact. He has enraged the philosophical community simply by defending the unexceptional. Here is a sampling of views he fiercely and proudly defends in the face of so-called academic achievement in fields as diverse as literary criticism, artificial intelligence, cognitive science, animal and child psychology, and of course, contemporary continental and analytical philosophy: the physical world is independent of its inhabitants and would continue to exist even if they did not (see Realism and antirealism); the world comprises facts which make statements and beliefs about it true or

false (see Truth, correspondence theory of); some statements are true solely because of what they mean, others because of the way the world is (see Analytic and synthetic); some translations are correct, others are incorrect; because and only because linguistic expressions have meaning, they can determinately apply to things in the world (see Reference); thoughts are in the head (internalism); because thoughts are (individuated by factors) in the head, it is (logically) possible that we are radically deceived about (the nature of) the external world (see Scepticism); I am (or can be) consciously aware of my thoughts and feelings in a way that others cannot (see Introspection, epistemology of); small children and some animals think and feel; one couldn't have a mind in virtue of running a computer program (see Chinese room argument); mental phenomena are just biological phenomena - that is, higher-level features of the brain - and so, studying the mind is studying the brain (biological naturalism); but since Searle maintains a logical distinction between mental and neurophysiological predicates, neurophysiology wouldn't give one any philosophical or conceptual insight into mental phenomena.

That it has become fashionable to contradict the views Searle defends might amaze a novice to philosophy. Even more amazing is that, though speech act theory has become academically fashionable (more in linguistics than in philosophy), it is Searle's defence of the unexceptional that has won him the reputation of philosophical maverick. Some have branded Searle an iconoclast sans argumentation, as philosophically unsubtle and obtuse. But with unflinching commitment, Searle defiantly rejects any philosophy that controverts the commonplace. Searle, not unlike J.L. Austin, Wittgenstein and Moore before him, looks to philosophy for analytic clarification, not metaphysical reduction or elimination.

Second- and higher-order logics

In first-order predicate logic there are symbols for fixed individuals, relations and functions on a given universe of individuals and there are variables ranging over the individuals, with associated quantifiers. Second-order logic adds variables ranging over relations and functions on the universe of individuals, and associated quantifiers, which are called second-order variables and quantifiers. Sometimes one also adds symbols for fixed higher-order relations and functions among and on the relations, functions and individuals of the original universe. One can add third-order variables ranging over relations and functions among and on the relations, functions and individuals on the universe, with associated quantifiers, and so on, to yield logics of even higher order. It is usual to use proof systems for higher-order logics (that is, logics beyond first-order) that include analogues of the first-order quantifier rules for all quantifiers.

An extensional n-*ary relation variable in effect ranges over arbitrary sets of* n-*tuples of members of the universe. (Functions are omitted here for simplicity: remarks about them parallel those for relations.) If the set of sets of* n-*tuples of members of a universe is fully determined once the universe itself is given, then the truth-values of sentences involving second-order quantifiers are determined in a structure like the ones used for first-order logic. However, if the notion of the set of all sets of* n-*tuples of members of a universe is specified in terms of some theory about sets or relations, then the universe of a structure must be supplemented by specifications of the domains of the various higher-order variables. No matter what theory one adopts, there are infinitely many choices for such domains compatible with the theory over any infinite universe. This casts doubt on the apparent clarity of the notion of 'all* n-*ary relations on a domain': since the notion cannot be defined categorically in terms of the domain using any theory whatsoever, how could it be well-determined?*

1 Standard second-order logic

Only second-order quantification over relations will be discussed here. Higher-order quantification and quantification over functions can be treated in an entirely parallel way. Symbols for higher-order relations and functions will be omitted for simplicity. Supplement the language of first-order predicate logic (see Predicate calculus) with variables X_n^m for *m*-ary relations, for all natural numbers *m* and *n*. Add to the definition of a formula of first-order predicate logic that, for all natural numbers *m* and *n*, $X_n^m t_1 \ldots t_m$ is an atomic formula, where each t_i is a constant symbol or first-order variable; and that if ϕ is a formula, then so are $(\forall X_n^m)\phi$ and $(\exists X_n^m)\phi$. Free and bound second-order variables are defined in exact parallel to the definitions for first-order variables, and a sentence is a formula with no free variables of any order.

It will be convenient always to require of any given language that there be infinitely many relation symbols of each possible number of places and infinitely many constant symbols not in it. The definition of truth in a structure for first-order predicate logic is extended to the *standard semantics* for second-order logic by supplying additional clauses for second-order quantification as follows. Consider a structure A with language $\mathcal{L}$. Let *P* be some definite *m*-placed relation symbol not in $\mathcal{L}$, and define $\psi(P)$ to be the sentence which results from replacing every free occurrence of X_n^m in ψ by *P*.

(1) If the sentence ϕ is of the form $(\forall X_n^m)\psi$ for some *m* and *n*, then the truth-value of ϕ is T if the truth-value of $\psi(P)$ is T in every expansion of A to a structure the language that includes every member of $\mathcal{L}$ and also *P*. It is F otherwise.
(2) If the sentence ϕ is of the form $(\exists X_n^m)\psi$ for some *m* and *n*, then the truth-value of ϕ is T if the truth-value of $\psi(P)$ is T in at least one expansion of A to a structure for the language that includes every member of $\mathcal{L}$ and also *P*. It is F otherwise.

Once given the standard semantics a logical truth is defined to be a sentence true in every structure for the language of the sentence and a valid argument to be one such that there is no structure in which all the premises are true and the conclusion false, as for first-order logic. Moreover, since the notion of structure is unchanged from first-order logic, standard model-theoretic notions such as isomorphism and categoricity can be taken over unchanged from the model theory of first-order logic. (Two structures are said to be isomorphic if, roughly, there is a one-to-one correspondence between their universes that takes the interpretations of constant and relation

symbols in one to the corresponding interpretations in the other. A theory is said to be categorical if all its models are isomorphic.)

It is natural to turn now to a deductive system for second-order logic to characterize logical truths and valid arguments. This does not work out nearly so well for second-order logic as for first-order.

The core of any deduction system for second-order logic will be a first-order system supplemented with quantifier rules for the second-order quantifiers that exactly parallel those for the first-order ones, with *n*-placed relation symbols playing the role constant symbols did for first-order quantification in the case of second-order quantification over *n*-ary relations.

In standard second-order logic one assumes that for any formula ϕ with all of its free variables from the list $v_1, \ldots, v_m, v_{m+1}, \ldots, v_{m+n}$ and for any *n* individuals $b_1, \ldots, b_n$, there exists an *m*-ary relation comprehending exactly those *m*-tuples of individuals $a_1, \ldots, a_m$ which are such that

$$\phi[a_1, \ldots, a_m, b_1, \ldots, b_n]$$

holds, where the square brackets indicate that v_1 is replaced everywhere it occurs free in ϕ by a new constant symbol interpreted by a_1 in an expanded structure, and so on. The relation is said to be defined by ϕ with parameters $b_1, \ldots, b_n$. More precisely, one assumes that the following axiom schema of comprehension holds:

$$(\forall v_{m+1}) \ldots (\forall v_{m+n})(\exists X_1^m)$$
$$(\forall v_1) \ldots (\forall v_m)(X_1^m v_1 \ldots v_m \leftrightarrow \phi),$$

where *m* and *n* are natural numbers and ϕ is a formula with all of its free variables among $v_1, \ldots, v_{m+n}$. If the variables $v_1, \ldots, v_m$ do not occur in the formula ϕ, then the comprehension axiom entails that the empty *m*-ary relation is in the domain of the second-order variables when ϕ does not hold of $b_1, \ldots, b_n$, and that the universal *m*-ary relation is in the domain of the second-order variables when it does hold.

It is enough for many purposes to consider only the predicative axiom schema of comprehension, which requires additionally that ϕ be a formula that does not contain any second-order quantifiers.

One might add other axioms to a deduction system for second-order logic. However, there is no usable system of axioms that yields all the logical truths as theorems: if a deduction system for second-order logic is *sound* (that is, if it cannot be used to derive sentences that are not logical truths) and the theorems are recursively enumerable (that is, there are effective procedures for listing the axioms and checking deductions - see Computability theory), then it is incomplete in the sense that there is a logical truth that cannot be deduced in it.

The impossibility of providing a complete deduction system for second-order logic follows from Gödel's incompleteness theorems (see Gödel's theorems §§3-4) and the fact that there is a second-order sentence that is a categorical axiomatization of arithmetic (that is, an axiomatization such that any model is isomorphic to a model with universe the set of natural numbers with, say, for definiteness, the relation 'strictly less than' and the addition and multiplication operations - in less technical terms, this is an axiomatization that characterizes the natural numbers completely for all mathematical purposes). (A sentence that is a categorical axiomatization of arithmetic is described and discussed in §3 below.) Suppose the sentence Φ is a categorical axiomatization of arithmetic. A truth of arithmetic is just a sentence true of the natural numbers. Thus, a sentence ϕ is a truth of arithmetic just if it is true in every model of Φ, that is, just if the argument from Φ to ϕ is valid. But that means that a complete deduction system for second-order logic would yield a decision procedure for the truths of arithmetic: ϕ is true if deducible from Φ and not true if $\neg\phi$ is deducible from Φ, and a systematic enumeration of all possible deductions from Φ will eventually decide which of these is the case. Gödel's incompleteness theorem entails that no such decision procedure is possible, and so no such deduction system is possible.

2 Alternative semantics

Instead of requiring, as in the standard semantics, that second-order variables range over all relations on a domain, one can be more explicit about their range by specifying as part of a structure the domains of the second-order variables in addition to that for the first-order variables. A Henkin structure for second-order logic is, by definition, an ordinary structure (with a universe and an interpretation function) supplemented by a third

component: a domain function $\mathcal{D}$ on the natural numbers that takes each natural number *n* to a set of *n*-ary relations on the universe of the structure. For each natural number *n*, the set $\mathcal{D}(n)$ must contain every *n*-ary relation that is the interpretation of an *n*-placed relation symbol in the language of the structure. (This condition is frequently omitted. But no use is ever made of the Henkin structures that do not satisfy it.)

Let A be a Henkin structure with language $\mathcal{L}$, and let *P* and $\psi(P)$ be as above. In Henkin semantics, the clauses of the definition of truth for the quantifiers will be

(1′) If the sentence ϕ is of the form $(\forall X_n^m)\psi$ for some *m* and *n*, then the truth-value of ϕ is T if the truth-value of $\psi(P)$ is T in every expansion of A to a Henkin structure for the language that includes every member of $\mathcal{L}$ and also *P* and interprets *P* by a member of $\mathcal{D}(n)$. It is F otherwise.
(2′) If the sentence ϕ is of the form $(\exists X_n^m)\psi$ for some *m* and *n*, then the truth-value of ϕ is T if the truth-value of $\psi(P)$ is T in at least one expansion of A to a Henkin structure for the language that includes every member of $\mathcal{L}$ and also *P* and interprets *P* by a member of $\mathcal{D}(n)$. It is F otherwise.

One can define a Henkin logical truth to be a sentence true in every Henkin structure for the language of the sentence and a Henkin valid argument to be one such that there is no Henkin structure in which all the premises are true and the conclusion false. If one were to restrict attention to *full* Henkin models - in which for each *n* the value of $\mathcal{D}(n)$ is the set of all *n*-ary relations on the domain - one would recover the logical truths and valid arguments of standard second-order logic. There are possibilities intermediate between considering all Henkin structures and considering only full ones: for example, that of restricting attention to Henkin structures that are models of the comprehension schema.

The second-order quantification of Henkin semantics resembles first-order quantification in that the universe of quantification is specified. That suggests going even further - to a first-order semantics for (syntactically) second-order logic. The domains of *n*-ary relations of Henkin structures are here replaced by perfectly arbitrary domains of objects - no longer required to be relations on the universe of individuals - and the atomic formulas of the form $X_n^m t_1 \ldots t_m$, which are now just of the semantic form of a list of $m+1$ first-order constants and variables, are interpreted using what are called ‘predication relations’ (which should really be called ‘relation relations’ but are not, for obvious reasons). For example, $X_n^m v_1 \ldots v_m$ becomes $P_m X_n^m v_1 \ldots v_m$, where P_m is the predication relation for *m*-ary relations, which may be read ‘the relation X_n^m holds of $v_1, \ldots, v_m$’.

Once there are predication relations, there is no need to introduce any other relations, except as objects in the first-order domains - all the relations can be taken to be members of the universes of the second-order variables. It is therefore possible to assume that the only relation symbols in a first-order structure for second-order logic are those for the predication relations and equality. This is not absolutely essential, but it does simplify matters considerably. A *first-order structure for second-order logic* will be constituted, as usual, of a non-empty universe of individuals, a domain function $\mathcal{D}$ on the natural numbers that takes each number to a non-empty set, and an interpretation function. The interpretation function interprets constant symbols as members of the various universes, and it interprets each predication relation symbol P_n as a relation that can hold only between a member of $\mathcal{D}(n)$ and *n* members of the universe of individuals, that is, the interpretation of each P_n is a set of $n+1$-tuples with first members from $\mathcal{D}(n)$ and all other members from the universe of individuals.

A Henkin structure can be converted into a first-order structure for second-order logic as follows. The domain function $\mathcal{D}$ is simply the domain function of the Henkin structure. The predication relations are based on membership relations: the *n*th predication relation holds between $R \in \mathcal{D}(n)$ and *n* objects just if the *n*-tuple formed by the *n* objects is a member of *R*. Each *n*-placed relation symbol must be replaced by a constant symbol that has the same interpretation, now viewed as a member of $\mathcal{D}(n)$. The semantics for second-order logic with first-order structures is just a standard first-order semantics for a multi-sorted structure, that is, one with many universes. The variables associated with a given universe (in our example, variables X_m^n are associated with $\mathcal{D}(n)$) are only interpreted by (or replaced by constant symbols interpreted by) members of that universe. The device of using many universes instead of one involves less than meets the eye: it is possible using entirely elementary methods to replace structures with many universes with ordinary single-universe structures that are equivalent in a suitably strong sense.

One can make use of intensional first-order structures for second-order logic, but here we restrict our attention to

extensional ones, which are, by definition, those that are models of the following schema:

$$(\forall X_1^n)(\forall X_2^n)((\forall v_1)\dots(\forall v_n)$$
$$(X_1^n v_1 \dots v_n \leftrightarrow X_2^n v_1 \dots v_n) \rightarrow X_1^n = X_2^n).$$

The schema says that relations that hold of the same *n*-tuples are identical.

In extensional first-order structures for second-order logic, the set of *n*-tuples of which a relation holds fully determines the relation, and so extensional first-order structures for second-order logic might as well just be Henkin structures: every such structure A gives rise to a Henkin structure by dropping the predication relations and, for each *n*, replacing each member *R* of $\mathcal{D}(n)$ by the set of all *n*-tuples $(a_1, \dots, a_n)$ such that $(R, a_1, \dots, a_n)$ is in the *n*th predication relation of the first-order structure. Constant symbols that stand for objects in $\mathcal{D}(n)$ must be replaced by *n*-placed relation symbols that are interpreted as the relations corresponding to the given objects. The resulting Henkin structure, converted to a first-order structure by the procedure described above, yields a first-order structure suitably similar to the original structure A.

3 Metamathematics

Dedekind observed that a set is finite if and only if there is no one-to-one correspondence between the set and any of its proper subsets. Thus, the following formula, $\Psi(X_1^1)$, on the standard semantics, expresses that the predicate X_1^1 holds of finitely many things:

$$(\forall X_1^2)(((\forall v_1)(X_1^1 v_1 \rightarrow (\exists v_2)(X_1^1 v_2 \wedge X_1^2 v_1 v_2))$$
$$\wedge (\forall v_1)(\forall v_2)(\forall v_3)(X_1^2 v_1 v_2 \wedge X_1^2 v_1 v_3 \rightarrow v_2 = v_3)$$
$$\wedge (\forall v_1)(\forall v_2)(\forall v_3)(X_1^2 v_1 v_3 \wedge X_1^2 v_2 v_3 \rightarrow v_1 = v_2))$$
$$\rightarrow (\forall v_2)(X_1^1 v_2 \rightarrow (\exists v_1)(X_1^1 v_1 \wedge X_1^2 v_1 v_2))).$$

Using this formula one can categorically axiomatize the natural numbers as a discrete linear order with a least element and no greatest element (‘discrete’ means that every element that has a predecessor (successor) has an immediate predecessor (successor)) in which the set of elements less than any element is finite. One can then supplement this with standard first-order axiomatizations of, for example, addition and multiplication. It is straightforward to give a first-order axiomatization of the discrete linear orders with a least element and no greatest element. The only second-order part of the categorical axiomatization is the use of the notion of finitude. That is our main concern here.

Note that on the Henkin interpretation of second-order logic $\Psi(X_1^1)$ does not define finitude: in order for the definition to work, it is crucial that the domain of the variable X_1^2 include relations that yield *all* one-to-one correspondences from X_1^1 to itself. To give a trivial example, $\Psi(X_1^1)$ holds vacuously of any set - including an infinite one - in a Henkin structure in which there simply are not any binary relations that relate objects in the set to other objects in the set. It is clear that this example may in some sense be taken to be artificial. Indeed, the constraints we have placed on which Henkin structures are to be allowed exclude ones in which there are no binary relations whatever on some part of the universe. But if constraints are to be imposed axiomatically - that is, by restricting attention to Henkin models of some set of axioms - then no constraints help to ensure that Ψ, or indeed any other formula, characterizes finitude. Any suitable axiomatic constraints would, as was in effect shown in §2, carry over into first-order axiomatic constraints such that finitude could be characterized over the first-order structures for second-order logic that satisfy them.

But the notion of finitude cannot be characterized axiomatically in first-order logic, since first-order logic is *compact*. The compactness theorem for first-order logic states that if every finite subset of a set of sentences of first-order logic has a model, then so does the whole set. Suppose a set *S* of sentences of first-order logic has models in which the interpretation of a predicate symbol *P* is of arbitrarily large finite size. Let S' be the set of sentences including those in *S* plus sentences of first-order logic formalizing ‘There is at least one thing *v* such that $P(v)$’, ‘There are at least two things *v* such that $P(v)$’, and so on. Then every finite subset of S' has a model. But then by the compactness theorem the whole set has a model, in which the extension of *P* must be infinite. So if a set *S* of sentences of first-order logic has models in which the interpretation of *P* is of every finite size then it has a model in which the interpretation of *P* is infinite. It fails to characterize finitude. (See Model theory.) Thus, the

notion of finitude cannot be axiomatically characterized in second-order logic interpreted using either first-order or Henkin structures.

By a contraposition of this argument, since finitude can be characterized in standard second-order logic, standard second-order logic is not compact. Thus, a sentence of standard second-order logic can be a logical consequence of infinitely many sentences of standard second-order logic without being a consequence of any finite subset of them. This is a very strong failure of the very idea of having a deduction system for standard second-order logic.

In §1, it was shown that no deduction system captured the logical truths of standard second-order logic. It now follows that standard second-order logic is also difficult to characterize in a second sense: the Henkin structures that are associated with standard second-order logic - the full Henkin structures - cannot be characterized axiomatically, in the sense that there is no set of axioms, not even the set of all the logical truths of standard second-order logic, that hold of all and only the full Henkin structures. That follows because if there were such a set of axioms (since finitude can be characterized in standard second-order logic) they could be used to characterize axiomatically the notion of finitude.

The situation is entirely similar with many other familiar mathematical notions: like finitude, many notions that mathematicians seem to feel they understand have adequate definitions in standard second-order logic but not in first-order logic.

Secondary qualities

Primary qualities are generally defined as those properties that objects have independently of being perceived. Standard examples would include properties of shape, weight, position, electric charge, atomic structure. These properties characterize the way the world is in itself, separately from mind. Secondary qualities, by contrast, are defined as those properties that incorporate sensory responses in their conditions of application, so that the idea of a perceiver is built into their nature. It is more controversial which properties, if any, belong to this category, since not all philosophers agree that the standard alleged examples of secondary qualities - colours, sounds, tastes, smells, feels - are really correctly so classified. Some thinkers hold that objects have only primary qualities. Let us note the significance of the question, concentrating on the case of colour, which is the one most frequently discussed.

Objects appear to have both shape and colour in equal measure, but is this really how things are? Depending upon how we answer this question, we get very different pictures of the relation between appearance and reality. If both sorts of property are equally out there, equally objective, then what appears to us in perception is reality itself. When we see a material object we see something that exists independently of our seeing it, and we see the object as it is whether or not there are (or even could be) any perceivers. But if the colour of the object is inherently dependent upon our sensory responses, then the question arises as to whether what we see is really in some way itself mental. If colour is a secondary quality, in other words, do we see things as they really are? What is it that bears colour if colours are in some way mentally constituted? Do we indeed see anything at all, as distinct from introspecting the features of our own subjective states?

1 Some theories

To the question, ‘What is colour?’, a number of answers might be given; we shall mention five, and then offer some evaluation of them.

(1) An answer that appeals to the disciple of science is that to be red is to instantiate some physical property of surfaces and media - as it might be, reflecting or transmitting light of a particular wavelength. That is, whatever science says is the primary quality basis of colour in the object is literally identical with that colour. The case is thus analogous to other theoretical identifications with which we have become familiar, say heat with molecular motion or light with volleys of photons. Science has, on this view, discovered what redness really is, deep down in its hidden nature. Possibly, there is no one physical property to which redness reduces, since different types of red object might not be unified by any single physical property; in which case the proponent of the current theory will opine that it is the disjunction of each of the many physical properties that underlie redness in different objects with which redness is identical. When we see an object as red, then, we are seeing the relevant physical property as presenting a certain sensory appearance; but the redness itself has a nature that is not given to us in the sensory presentations we record with the word ’red’. Redness thus has an invisible nature, not revealed to ordinary perception. The seen is but the appearance of the unseen.

(2) Discomfort with a reducibility thesis of the previous kind is apt to prompt a claim of irreducibility. Just as some philosophers have felt that there is no alternative to accepting the ultimate irreducibility of mental states, so it might be thought that colour properties simply are what they are and not anything else: to be red is to be, precisely, red - period. Nothing more can be said, nor need it be. There is no doubt an operative causal basis of colour in objects, where this basis explains how light of certain wavelengths reaches the human eye; but it is not true that colour is simply identical with that basis. There are no informative identities of the kind envisaged by the previous theory. As with so many other concepts, colour concepts pick out their corresponding properties in the only way they can be picked out. Nothing is hidden in the nature of colour itself: how we see redness is how it is, *in toto*. Colours are not physical properties at all, save in the trivial sense that physical objects have them; they form an irreducible family of properties, not assimilable to properties of other kinds. In an important sense, they are inexplicable, primitive aspects of the way things are.

(3) Sensing a subjective ingredient in colour, some thinkers have gone to the extreme of denying outright that external objects are coloured; what bear colour properties are rather perceptual experiences themselves, episodes in the mind. Just as it is mental states to which the predicate ’pain’ properly applies (see Bodily sensations), so it is

states of mind that are rightly said to be red or green. Seeings themselves are what is coloured; or, put less bluntly, we must introduce items called 'sense-data' to serve as the bearers of colour, where sense-data are construed as inherently mind-dependent (see Sense-data). When we say that a tomato is red we make an error of projection, spreading the mind upon the world. This type of view will then naturally go all the way and accept that the shapes of things we see are also not properties of external objects, since the shaped object we see is surely identical with the coloured object we see - it is not like a case of one object lying behind another. It will turn out then that we are not perceptually acquainted with objects in the external world at all but only with items that dwell in our minds. If there are any external objects, we do not see them; indeed, given that we do not see them, we must face the question of what point there is in assuming their existence. Hence idealism - the denial of anything aside from minds and their states. Because of colour the ordinary world gets extinguished (see Idealism).

(4) A radical move now might be to deny that anything is ever coloured: not any physical object, because colour is too sense-dependent; and not any mental object, because then the objective world becomes invisible to us, at best a lurking presence shrouded in deep shadow. We are, to be sure, acquainted with colours in experience, but it is a mistake to think that anything has them, in the way that primary qualities are had. To experience a red tomato is like having a red after-image: there is colour in the offing in the latter case, but no physical thing is thereby red and nor is any mental thing. Colour might be compared with a medium through which you see things; it is not a property of what is seen or of the seeing of it. Colour is like perspective, a mode of seeing rather than a thing seen. When we say that the tomato is red we can only mean that it is presented though the medium of redness - from that chromatic perspective, as it were - not that it literally instantiates a property. Colour terms are more like adverbs of seeing than adjectives of objects: just as we see things clearly, so we see things redly (see Mental states, adverbial theory of).

(5) The final theory has been historically the most popular: it attempts to register the subjectivity inherent in colour while not denying that external objects are the proper bearers of colour. By situating colours as deftly as possible between the external object of perception and the inner experience of seeing, the theory aims to preserve as much as possible of our common-sense view of the world. Colours, on this theory, are dispositions that objects have to cause sensory responses in perceivers under appropriate conditions of lighting and perceptual receptivity. Objects have physical properties that interact with light and thence with our nervous systems to produce colour experiences in us: for an object to have a given colour is then for it to have a certain complex relational property - that of having the physically grounded capacity to produce specific modes of experience in suitably placed perceivers. To be red is to have the disposition or ability to appear red to perceivers in virtue of properties that do not themselves include the property of being red - such as reflecting certain wavelengths of light. Colours are thus like such properties as fragility, digestibility, potency - powers to produce specific effects. They are indeed in objects, since it is the object that has the disposition, but they are defined by reference to the sensory effects that objects produce, so that an element of subjectivity is introduced. In effect, they are higher-order psychophysical properties - logical constructions from a (possibly variable) physical basis and a specific sensory type. The mistake of the other theories was to regard colours as monolithic non-relational properties; once we recognize their complex psychophysical relational character colours can be everything we want them to be. Out there, yes; but also rooted in what is in here.

2 Assessment

We shall mention here just a few of the salient problems with each approach. Theory (1) suffers from two main problems: first, it makes our knowledge of the nature of colour overly conjectural and empirically vulnerable; second, it imposes an absoluteness on colour concepts that they cannot plausibly bear. Thus, to take the first, if red is constituted by some underlying micro-property, then we do not know the true nature of red until we know the identity of that micro-property; and we do not know how red relates logically to other colours until we know how the underlying micro-properties relate. But both of these consequences are highly counterintuitive. And, secondly, when we consider a hypothetical case in which the same micro-property systematically interacts with various nervous systems so as to produce different types of experience from case to case, we find that our intuitions favour the idea that in such circumstances the perceivers in question would speak truly in predicating of the objects a colour property that matches their experience, not one that matches the experience of some other privileged group of perceivers. Less cumbrously put, if things that look red to us look green to Martians, in virtue of our different sensory systems, then Martians speak truly when they describe as green what we describe (truly) as red. Truths

about colour are relative, while micro-properties are absolute, so the former cannot be identical to the latter. To be more exact, given that a particular colour is essentially the colour it is - which seems hard to deny - we cannot allow that different micro-properties might constitute the same colour or the same micro-property different colours.

Theory (2) ventures little and so risks little: its chief failing, viewed as offering the whole truth, is that it turns its face against a plain conceptual connection, namely that between the colour of an object and how it appears to perceivers. As we have just noted, colour truths are sensitive to the facts of sensory response, and simply declaring them irreducible does nothing to accommodate that constitutive connection. The dispositional theory, by contrast, explicitly builds the link to experience into its definition of colour, thus acknowledging what the simple irreducibility theory ignores.

The trouble with theory (3) has already been indicated: it cuts us off perceptually from the real world, by making the proper objects of sight purely mental. And there is this correlative problem: if mental items are what bear colour, and if what bears colour is the same as what bears shape, then we are committed to holding that mental items instantiate primary qualities too. Not only are bits of my mind red - they are also spherical and hollow and heavy. But that is surely false, even a category-mistake: no experience of a red sphere can itself be a red sphere, on pain of cramming the mind with spatially extended objects, with all that that implies. The theory roundly conflates what an experience is of with the experience itself, with the absurd result that the mind comes to be credited with all the properties of the physical world.

Theory (4) is an obscure and desperate attempt to wriggle out of the kinds of problem just rehearsed. No matter where we put the colour property we get into trouble, so put it nowhere! Here the difficulty is immediate: surely it is excessively revisionary to maintain that colour words are incapable of predicating properties of anything. Grammatically they are just like other predicates, and we have no hesitation in saying that what we are seeing is red, just as it is spherical. When you perceive a multi-coloured expanse you surely experience something as having various colours; so your experience itself would have to be grossly delusory if this were, in truth, not so. Your experience is certainly not as of there being colourless things viewed through a coloured filter (whatever that might mean). The phenomenology of colour experience, as well as the language of colour, is powerfully object-ascriptive - as much so as for primary qualities.

The dispositional theory aims to preserve this feature of colour by identifying colours with relational properties of objects, while not severing the link with sensory response. It also allows us to accord the right kind of epistemological status to our knowledge of colour, since we know our own experiences with an immediacy that is not vulnerable to empirical upset. Relativity to perceivers is explicitly registered, as is the need for a categorical physical base in the object. Theory (5) thus appears to paint colour in the right hues, locating it at the appropriate juncture between subjective and objective.

But there is a fly in the ointment, which concerns the phenomenology of colour experience. For ordinary visual experience does not, on the face of it, present colours to us in the way they intrinsically are according to that theory: a red object does not look as if it instantiates a complex relational disposition in respect of appropriate perceivers; it looks, rather, as if it instantiates a simple monadic property of the object’s local surface. Indeed, dispositions do not in general look any way at all (consider solubility), while colour is paradigmatically perceptual, seeming to inhere firmly in the seen object and nowhere else. This would not be such a problem if we did not hold that you can tell the nature of colours just by seeing them - that they are transparent to perception. But that axiom of common sense is put under pressure if their nature is declared to be intrinsically relational, since this is not how they appear. Should we then give up the assumption of the perceptual transparency of colour, or should we conclude that the dispositional theory gets the colours wrong? Neither alternative delights the spirit. What we need, ideally, is a way to retain the benefits of the dispositional theory while avoiding its revisionary consequences. How can colours be dispositions and yet not look like them, given that they have to look the way they are?

This may seem a difficult feat to accomplish; the authority of colour vision seems to set an impossibly high standard for the dispositional theory to meet. But there does, happily, appear to be a way through the problem, which requires but a little delicacy in formulating the purport of the dispositional theory. Typically, the theory is propounded in a strong form, as maintaining an identity thesis as between the property of being red and the

property of having a categorically based disposition to appear red in certain circumstances to perceivers. The problem, then, is that this putative identity is not borne out by colour experience itself, which sets a condition of adequacy for any account of the kind of property redness is. Might we weaken the theory so as to relinquish any claim of identity while preserving the conceptual link we want to respect? We might indeed: let us say that being red is *dependent* upon the corresponding disposition but not identical with it. Or, to bring out the analogy with a similar strategy in the philosophy of mind, let us say that colour properties are supervenient upon the corresponding dispositions but they are not reducible to those dispositions - in somewhat the way that pain is supervenient on brain states yet is not reducible to them (see Supervenience; Supervenience of the mental). Moreover, let us add that the dependence in question is conceptual, so that we can recognize it to hold a priori. Thus nothing else has to be true of an object for it to be red than that it instantiates the right disposition, but it does not follow from this - and is not true - that the colour is the disposition. In other words, we combine an irreducibility thesis about the colour property itself, after the fashion of theory (2), with a dependency claim about what disposition that property necessarily covaries with. Accordingly, the colour essentially depends upon the relational disposition but it does not thereby inherit all the logical features of what it depends upon. And this allows us to say that the colour is itself a simple monadic property of surfaces, which is precisely how it appears, while its instantiation is wholly controlled by a complex disposition that has no perceptual counterpart (is not seen). Note that the disposition does not constitute the hidden nature of the colour, since it is not identical to it; rather, it provides an extrinsic condition that nevertheless completely fixes the distribution of colours across the world. It is indeed a conceptual truth that colours map on to dispositions to appear, but we need not infer that we have any collapse of the former into the latter. Insisting on this logical gap enables us to respect colour experience to the hilt while recognizing the important vein of truth in the dispositional theory. Here, as elsewhere, holding philosophical explication to the strict standard of reduction - with the identity relation prized as the only respectable relation to invoke - leads to implausibility in our account of the concept at issue. Beguiling to the philosophical imagination though identity is, it is not the only relation that can serve our philosophical purposes. We need to acknowledge a hierarchy of distinct properties here - from categorical physical basis in the object to perceiver-relative disposition to simple colour property - instead of just so many descriptions of a single property.

3 Consequences

Having canvassed the options and hit upon the most lissom one, let us satisfy ourselves that matters have worked out as we would wish. Does the non-reductive dispositional theory leave us where we are content to rest? For it does have one large metaphysical implication that some may find disturbing, namely that the world cannot be divided exhaustively into a mental part and a physical part. On the pure dispositional theory, colour properties turn out to be constructions from physical bases in the object and sensory responses in perceivers, so that a fundamental metaphysical dualism is observed. But if colour properties are strictly irreducible to such dispositions, then there are properties in the world that are neither mental nor physical nor a combination of both. These properties belong to a third great category, not reducible to the other two. True, colours depend upon properties from the other two categories, but that is by no means the same as belonging to them; they are, as it were, emergent with respect to mental and physical properties. Thus, if we are asked whether colours are inherently subjective on the theory in question, the only correct answer is that strictly speaking they are not; though they may be rated as subjective in the weak sense that their conditions of instantiation include subjective facts. Metaphysically, then, colours force a pluralism of properties into our ontology, exceeding the limits of the mental and the physical.

This result has consequences for a general materialism (see Materialism). It is commonly assumed, by those who favour a dispositional theory of colour, that colours would come within a materialist ontology if experiences themselves could be brought within that ontology. But that is not quite right if colours are construed according to the weaker dispositional theory, since even if experiences themselves were wholly physical it would not follow that the colours they fix are themselves physical, on account of the non-identity of colours with their corresponding dispositions. Materialism would fail even for material objects, even if it could be made to work for the mind.

Colour logic comes out satisfactorily under the weak dispositional theory, perhaps even more so than under the strong version. For the weak version allows us to hold on fully to the idea that we know, ahead of doing any science, what the intrinsic nature of each colour is, and hence how the various colours relate to each other in terms of exclusion, similarity, and the like. No knowledge of the underlying micro-properties is needed; nor indeed are

we required to translate colour talk into sensory disposition talk. What we know of colour logic is thus derived directly from our acquaintance with colours as they are presented to us in all their simplicity; there is no call to reformulate such necessities into other terms (though there is a sense in which they have their origin in experiential necessities).

Second-order logic, philosophical issues in

Typically, a formal language has variables that range over a collection of objects, or domain of discourse. A language is 'second-order' if it has, in addition, variables that range over sets, functions, properties or relations on the domain of discourse. A language is third-order if it has variables ranging over sets of sets, or functions on relations, and so on. A language is higher-order if it is at least second-order.

Second-order languages enjoy a greater expressive power than first-order languages. For example, a set S of sentences is said to be categorical if any two models satisfying S are isomorphic, that is, have the same structure. There are second-order, categorical characterizations of important mathematical structures, including the natural numbers, the real numbers and Euclidean space. It is a consequence of the Löwenheim-Skolem theorems that there is no first-order categorical characterization of any infinite structure. There are also a number of central mathematical notions, such as finitude, countability, minimal closure and well-foundedness, which can be characterized with formulas of second-order languages, but cannot be characterized in first-order languages.

Some philosophers argue that second-order logic is not logic. Properties and relations are too obscure for rigorous foundational study, while sets and functions are in the purview of mathematics, not logic; logic should not have an ontology of its own. Other writers disqualify second-order logic because its consequence relation is not effective - there is no recursively enumerable, sound and complete deductive system for second-order logic.

The deeper issues underlying the dispute concern the goals and purposes of logical theory. If a logic is to be a calculus, an effective canon of inference, then second-order logic is beyond the pale. If, on the other hand, one aims to codify a standard to which correct reasoning must adhere, and to characterize the descriptive and communicative abilities of informal mathematical practice, then perhaps there is room for second-order logic.

1 First-order and second-order logic compared

The downward Löwenheim-Skolem theorem states that if *S* is a set of first-order sentences that has an infinite model, then *S* has a model whose domain is at most countably infinite (or the cardinality of *S*, whichever is larger). The upward Löwenheim-Skolem theorem states that if *S* is a set of first-order sentences such that, for each natural number *n*, *S* has a model whose domain has at least *n* elements, then for every infinite cardinal κ, *S* has a model whose domain has cardinality at least κ. It follows that no set of first-order sentences that has an infinite model is categorical. (A set of sentences is said to be categorical if any two models satisfying it are isomorphic.)

There is a complete, sound and effective deductive system *D* for first-order logic (see Predicate calculus). That is, if *S* is a set of sentences and ϕ is a single sentence, then ϕ is deducible from *S* in *D* if and only if ϕ holds in every structure that satisfies every member of *S*. Finally, first-order logic is compact, in that for every set *S* of first-order sentences, if every finite subset of *S* has a model, then *S* itself has a model.

(In standard semantics for second-order languages, the set or predicate variables range over the entire power set of the domain. It follows that the domain of discourse determines the range of the other variables. There is an alternative semantics, due to Leon Henkin (1950), in which this does not hold. Each model consists of not only a domain of discourse, but also separate ranges for the predicate, relation and function variables. With Henkin semantics, second-order logic is complete and compact, and the Löwenheim-Skolem theorems hold. In effect, with Henkin semantics, second-order languages are treated as multi-sorted first-order languages. The foregoing discussion presupposes standard semantics.)

Second-order logic has none of the above properties. The upward Löwenheim-Skolem theorem fails because there is a categorical characterization *AR* of the natural numbers. Every model of *AR* is countably infinite. The downward Löwenheim-Skolem theorem fails because there is a second-order categorical characterization *AN* of the real numbers. Every model of *AN* has the cardinality of the continuum, and so is uncountable (see Cantor's theorem; Continuum hypothesis). A corollary of these features, and Gödel's incompleteness theorem, is that second-order logic is not complete (see Gödel's theorems §1). There is no effective, sound and complete deductive system for second-order logic. Likewise, second-order logic is not compact.

The sentence *AR* characterizing the natural numbers is a straightforward formalization of common informal

axiomatizations of arithmetic. The ‘second-order’ item is the induction principle, stating that if a property (set) *P* of numbers holds for (contains) zero and is closed under the successor function, then *P* holds for (contains) all natural numbers. In symbols,

$$\forall P[(P0 \mathbin{\&} \forall x(Px \rightarrow Psx)) \rightarrow \forall xPx].$$

In first-order arithmetic, this principle is replaced by a scheme. Every instance of

$$[\phi(0) \mathbin{\&} \forall x(\phi(x) \rightarrow \phi(sx))] \rightarrow \forall x\phi(x)$$

in which ϕ is a formula in the language of first-order arithmetic, is an axiom. Thus, first-order arithmetic has infinitely many axioms.

In the characterization *AN* of real analysis, the second-order item is the principle of completeness, stating that every non-empty set of real numbers with an upper bound has a least upper bound:

$$\begin{aligned}&(\forall P)\{(\exists xPx \mathbin{\&} \exists x\forall y(Py \rightarrow y \leq x))\\ &\qquad \rightarrow \exists x[\forall y(Py \rightarrow y \leq x) \mathbin{\&}\\ &\qquad\qquad \forall z(\forall y(Py \rightarrow y \leq z) \rightarrow x \leq z)]\}\end{aligned}$$

First-order real analysis is obtained by replacing the completeness axiom with the completeness scheme,

$$\begin{aligned}&(\exists x\phi(x) \mathbin{\&} \exists x\forall y(\phi(y) \rightarrow y \leq x))\\ &\quad \rightarrow \exists x[\forall y(\phi(y) \rightarrow y \leq x) \mathbin{\&}\\ &\qquad\quad \forall z(\forall y(\phi(y) \rightarrow y \leq z) \rightarrow x \leq z)]\end{aligned}$$

one instance for each formula ϕ that contains neither *x* nor *z* free.

The difference between, say, second-order real analysis and its first-order counterpart is that in the former one cannot directly state that every non-empty bounded set has a least upper bound. Instead, there is a separate principle for each such set which is definable by a formula in the language of first-order analysis. Since there are sets which are not definable, the first-order theory has models which are not isomorphic to the real numbers. Such structures are called ‘nonstandard models’ (see Löwenheim-Skolem theorems and nonstandard models).

One common characterization of finitude, due to Richard Dedekind, is that a set is finite if there is no one-to-one function from the set to a proper subset of itself. This can be rendered as a second-order sentence with no non-logical terminology:

$$\begin{aligned}&\mathrm{FIN}(X)\text{:}\ \sim\exists f[\forall x(Xx \rightarrow Xfx) \mathbin{\&}\\ &\qquad \forall x\forall y((Xx \mathbin{\&} Xy \mathbin{\&} fx = fy) \rightarrow x = y)\\ &\qquad\quad \mathbin{\&} \exists z(Xz \mathbin{\&} \forall x(Xx \rightarrow fx \neq z))]\end{aligned}$$

It follows from the compactness property that there is no first-order characterization of finitude.

2 Defence

It is widely held, often implicitly, that mathematicians succeed in describing various structures, up to isomorphism, and in communicating information about them. When various mathematicians refer to ‘the natural numbers’, ‘the real numbers’, ‘Euclidean space’ and so on, they are talking about the same structures. Similarly, there is little doubt that such mathematical notions as finitude and well-foundedness are clear, definite and unequivocal. In short, it is agreed that the *informal* language of mathematics is sufficient for ordinary description and communication of the basic structures and notions.

One purpose of logic, model theory in particular, is to ‘model’ the semantics of the informal languages of mathematics. Thus, one desideratum is that logic should somehow register the successful description and communication of mathematical structures and notions. As we have seen, first-order logic falls short of this. As Barwise and Feferman put it, ‘As logicians, we do our subject a disservice by convincing others that logic is first-order and then convincing them that almost none of the concepts of modern mathematics can really be captured in first-order logic’ (1985: 5).

A further claim is that it is unnatural to rely on infinitely many axioms, when a single second-order axiom is available. For example, if someone is asked why they believe that the second-order completeness axiom holds for the real numbers, the reply might be that the principle characterizes the numbers, perhaps citing the categoricity result. However, if asked why they believe every instance of the first-order completeness scheme, the answer is not that simple. One cannot claim that the scheme characterizes the real numbers since, as we have seen, the scheme does not characterize the numbers. Georg Kreisel suggests that the reason that mathematicians believe the instances of the various schemes is that they are consequences of the respective second-order axiom (1967). Indeed, in common deductive systems for second-order logic, each instance of each scheme can be deduced from the corresponding axiom. An opponent might retort that one can see from the scheme itself that all of its instances are true. This might be called a 'metalinguistic' move, since it invokes the scheme itself at the level of justification. Notice that this manoeuvre involves a generalization, since it refers to *all* instances of the scheme. It remains to be seen whether this generalization is any more problematic than the generalization over predicates, properties or sets. Notice also that the scheme itself is an infinite structure, and cannot be characterized in a first-order metalanguage.

Another problem with the schemes is that each one is tied to the ingredients of the particular language in use at the time. For example, if the induction scheme is formulated in a language whose only non-logical term is the successor symbol, then a very weak, decidable theory results. To obtain a richer system, closer to classical arithmetic, symbols for addition and multiplication must be added, and the induction scheme must itself be expanded to include instances with the new terminology. On the other hand, the second-order induction axiom, which contains only the successor symbol, is sufficient to characterize the natural numbers. Moreover, addition and multiplication can be defined in second-order arithmetic, as can any recursive function. Beyond that, new terminology can be added as needed, without having to modify the very definition of the natural numbers. This fits the intuition that one cannot tell in advance what resources, and thus what terminology, are needed to shed light on the natural numbers, even after the structure has been characterized.

In short, 'the natural numbers' has an informal interpretation that outruns what is captured in first-order arithmetic, and this informal interpretation plays a central role in actual mathematical practice. Alonzo Church agrees:

> our definition of the consequences of a system of postulates…can be seen to be not essentially different from [that] required for the…treatment of classical mathematics…. It is true that the non-effective notion of consequence, as we have introduced it…presupposes a certain absolute notion of ALL propositional functions of individuals. But this is presupposed also in classical mathematics, especially classical analysis
>
> (1956: 326)

3 Prosecution

A number of authors have either rejected second-order logic outright, or else claimed that it is not logic, but rather an obscure form of mathematics. One broad attack is aimed at 'traditional' versions of second-order and higher-order systems that have variables ranging over intensional items such as properties, attributes and propositional functions (see Intensional entities). There is no consensus on which properties, attributes and so on exist, and there is no consensus on when two properties are identical or distinct. These sticky metaphysical matters should not interfere with serious work in the foundations of mathematics, the argument goes. Mathematics itself is reasonably clear, and we should not invoke obscurity in order to develop foundations for it.

This argument does not affect contemporary systems. The items in the range of the second-order variables in standard semantics are extensional - they are sets or classes. For any collection *C* of elements of the domain of discourse, there is an item in the range of the 'property' variables whose elements are the members of *C*. The development of modern set theory shows that the extensional notion of class is at least relatively clear (see Set theory).

The problem now, however, is that by invoking set-theoretic notions in the model theory, we may have crossed a border from logic into mathematics. W.V. Quine calls second-order logic 'set theory in disguise' and 'set theory in sheep's clothing'. The metaphor suggests that, unlike grizzly mathematics, logic is, or ought to be, a mere 'sheep'.

Quine and others have brought a number of arguments for this judgment. One involves ontological commitment

(see Ontological commitment). A first-order theory, with an intended interpretation, has variables ranging over a given domain of discourse. A second-order theory, with standard semantics, has variables ranging over the entire power set of the domain, a larger collection. Moreover, the usual metatheory for second-order languages, where we turn for information about the power set operation, uses Zermelo-Fraenkel set theory (see Set theory, different systems of §3), which does have a vast ontology. As Quine puts it, 'Set theory's staggering existential assumptions are…hidden…in the tacit shift from schematic predicate letter to quantifiable set variable' ([1970] 1986: 68).

Because of the expressive resources of second-order languages, including the terminology for sets, there are a number of rather substantial mathematical statements that can be formulated in second-order languages. There is, for example, a sentence that is a logical truth if and only if the generalized continuum hypothesis is true, and there is a sentence that is a logical truth if and only if the axiom of choice holds. But it is on the face of it counterintuitive to hold that these statements are logically true or logically false.

It follows from Gödel's completeness theorem that the consequence relation of first-order logic is effective. The set of first-order logical truths, for example, is recursively enumerable. On the other hand, the set of second-order logical truths is not. The set is not even definable in (second-order) arithmetic, although it is definable in set theory. Again, we seem to be beyond the purview of logic (see Non-constructive rules of inference).

In summary, many of those who hold that second-order logic is not logic seem to agree that the *informal* language of mathematics is somehow adequate to describe and communicate the various structures and notions, but they add that logic must fail where informal mathematics succeeds. There is another line of argument, less popular today, that rejects the presupposition that the mathematical structures and notions in question are unequivocal. Accordingly, the Löwenheim-Skolem theorems indicate that there is no unambiguous notion of 'finite', 'countable', 'natural number' and so on. All of these notions are relative to a background (first-order) set theory. This sceptical view is sometimes called 'Skolemite relativism'. Advocates of it adopt first-order logic because they claim that its model theory accurately reflects the ontological/epistemic/semantic situation. There is nothing unequivocal to capture or describe with either formal or informal languages of mathematics.

4 Settlement?

By itself, a border dispute concerning mathematics may not be all that interesting. The deeper matters here concern the role and purposes of logical theory. Why do we develop logical systems in the first place? Historically, a number of goals have been articulated. One of these is to present a calculus, a deductive system to codify or serve as a canon of correct reasoning. In light of incompleteness, this goal is not served by the consequence relation of second-order logic (as long as a system must be effective, or recursive, in order to qualify as a calculus; see Church's thesis). There are, to be sure, good deductive systems for second-order languages, but they are all incomplete for standard semantics.

On the other hand, it is widely held that deductive systems must themselves adhere to a prior notion of logical consequence. This notion is often understood in modal terms. Near the beginning of the *Prior Analytics*, Aristotle defines a 'syllogism' to be 'a discourse in which, certain things having been supposed, something different from the things supposed results *of necessity*' (see Logic, ancient §§1-3). In advance of reflection, there is no reason to expect that the pre-theoretic, modal notion of logical consequence is effective, and that there is a complete deductive system for it. Advocates of second-order logic claim that the second-order consequence relation captures an underlying notion of logical consequence, one to which deductive systems must answer.

There is a trend in philosophy to understand at least some modality in terms of language. In particular, it is held by many that necessities are grounded in the meanings of terms. In this spirit, logical consequence is sometimes defined in terms of the meanings of a certain collection of terms, the so-called 'logical terminology'. This is consonant with the slogan that logical consequence is a matter of 'form'. The logical terminology of a discourse is what marks its form, while the non-logical items determine content. From this perspective, the issue of second-order logic is whether the membership (or predication) relation and bound variables ranging over classes are logical. This, of course, is another border dispute. It should be settled by examining the various systems, to determine which are the most useful and insightful accounts of logical consequence. Perhaps one can be eclectic (see Logical constants; Logical form).

Second-order, and even higher-order, languages have found applications outside of logic and the foundations of mathematics. Two noteworthy examples are Montague grammar, for natural language (1974; see Montague, R.M.), and Aldo Bressan's higher-order modal logic for the language of science (1972). Although, as noted, many logicians have come to see first-order logic as too weak, it is still widely held that the consequence relation of second-order logic is too intractable for useful mathematical study. A growing research programme in mathematical logic is to develop and study alternatives which are, in a sense, intermediate between first-order and second-order.

Selden, John (1584-1654)

Antiquarian, philologist, parliamentarian, legal historian and practising lawyer, John Selden was a major figure in the renaissance and systematization of common law. In jurisprudence, his importance lies in his attempt to develop certain elements of an epistemology of common law. He made use of history to criticize current legal doctrines, and developed a philosophical methodology in relation to the interpretation of precedent.

Educated at Oxford, Selden joined Clifford's Inn (1602) and Inner Temple (1604) and was called to the Bar in 1612. A friend of the historian William Camden and the antiquary Sir Robert Cotton, his historical writings were in large measure responses to the Reformation and to the vernacularization of English law.

Selden's work was in essence a nascent form of common law hermeneutics, a critical interpretation of legal texts and institutions. His use of philology to reconstruct the development of common law indicated not only that it was a member of the European tradition of law but also that, conceived as a tradition of judgment, English law was far more complex and diverse a cultural form than the insular profession of his day would allow. In his extra-legal writings, most notably in his posthumously published *Table Talk*, Selden did much to indicate the cultural significance of legal institutions.

In common with the historical and classicist tendencies of the Elizabethan era, Selden was concerned primarily to collect for posterity what he termed the neglected and fragmentary evidence of antique common law. In an early and in many respects exemplary work on the ancient constitution, *Jani Anglorum facies altera (The Other Face of the English Janus)* (1610a), he thus traced the inhabitants and laws of England through an imaginative and remarkably wide-ranging study of sources as diverse as mythology, literature, etymology and statuary inscriptions. The work explicitly placed the common law under the ambivalent sign of Janus and indicated in detail the diversity of nationalities and of languages that had played a part in the development of common law. The constitution was in his view plural and in many respects uncertain. The histories of English law which Selden subsequently wrote concentrated upon detailing the foreign influences and jurisdictions which subsisted within the common law. In his history of *The Duello or Single Combat* (1610b), he showed the importance of French law to English custom. In his *Titles of Honour* (1614) and in his editions of the early treatises *Fleta* and *De Laudibus Legum Angliae (In Praise of the Laws of England)* he indicated the pervasiveness of Roman influence. In *Mare Clausum (The Enclosed Sea)* (1636), his polemical tract directed against the famous treatise by Hugo Grotius on the freedom of the seas, Selden urged the use of natural law, while in *De Diis Syris (Of Syrian Gods)* (1617b) and in the *History of Tythes* (1618), his last major work, he argued for the importance of divine law (*ius divinum*). In each case the importance of historical research lay not simply in rectifying the neglect of evidence and precedent but also and more remarkably in providing a tool for the criticism of England's 'dulling custom' and of some of its substantive faults. He argued thus in *Jani Anglorum* for the recognition of the right of women to inherit public office, while elsewhere he urged reform of the law of tithes and more broadly supported an expansion of the historical method and sources of common law judgment.

It was Selden's lifelong belief that what he coined, in a work on *Titles of Honour*, as 'the Lady Common Law' could not lie alone but was rather to be understood as a member of a family of legal traditions whose ancestry could be traced across Europe and whose reason was both divine and human.

Self, Indian theories of

Hindu thought traces its different conceptions of the self to the earliest extant Vedic sources composed in the Sanskrit language. The words commonly used in Hindu thought and religion for the self are jīva *(life),* ātman *(breath),* jīvātman *(life-breath),* puruṣa *(the essence that lies in the body), and* kṣetrajña *(one who knows the body). Each of these words was the culmination of a process of inquiry with the purpose of discovering the ultimate nature of the self. By the end of the ancient period, the personal self was regarded as something eternal which becomes connected to a body in order to exhaust the good and bad karma it has accumulated in its many lives. This self was supposed to be able to regain its purity by following different spiritual paths by means of which it can escape from the circle of births and deaths forever.*

There is one more important development in the ancient and classical period. The conception of Brahman as both immanent and transcendent led to Brahman being identified with the personal self. The habit of thought that tried to relate every aspect of the individual with its counterpart in the universe (Ṛg Veda X. 16) had already prepared the background for this identification process. When the ultimate principle in the subjective and objective spheres had arrived at their respective ends in the discovery of the ātman *and Brahman, it was easy to equate the two as being the same spiritual 'energy' that informs both the outer world and the inner self. This equation had important implications for later philosophical growth.*

The above conceptions of the self-identity question find expression in the six systems of Hindu thought. These are known as āstikadarśanas *or ways of seeing the self without rejecting the authority of the Vedas. Often, one system or the other may not explicitly state their allegiance to the Vedas, but unlike Buddhism or Jainism, they did not openly repudiate Vedic authority. Thus they were* āstikadarśanas *as opposed to the others who were* nāstikadarśanas*. The word* darśana *for philosophy is also significant if one realizes that philosophy does not end with only an intellectual knowing of one's self-identity but also culminates in realizing it and truly becoming it.*

1 Vedic literature

Hindu thought traces most of its philosophical ideas to the time of the Vedas (*c*.2000-1000 BC) composed in Sanskrit. While the corpus called Vedic literature cannot be accurately classified, it is by convention considered to comprise the four Vedas (*Ṛg Veda*, *Atharva Veda*, *Yajur Veda*, *Sāma Veda*) along with the *Brāhmaṇas* (liturgical works), *Āraṇyakas* ('books composed in the forest') and Upaniṣads (philosophical literature) attached to each of the Vedas. The *Ṛg Veda*, which is uniformly considered to be the most ancient contains statements that formed, in some way, the basis of important notions of the self that were developed in the philosophical schools later (*c*.200-600 AD). By the time of the early Upaniṣads (*c*.800-400 BC) the different words used for the self were entrenched in Hindu thought. All the different genres of Vedic literature collectively enjoy a sacrality which is denoted by designating them as 'not the work of humans' (*apauruṣeya*) and by the fact that they were never written down at their time of origin. They were 'heard' (*śruti*) and are considered to be the result of the intuitive insight of the Vedic wise sages (*ṛṣis*); they were handed down orally from generation to generation and many methods were devised to preserve the accuracy of the texts.

There are many terms used to denote the individual self in Hindu thought; some of them are *jīva* (from the root *jīv* - to live, be alive), *ātman* (from the root *an* - to breathe), *jīvātman* (combining the first two), *puruṣa* (from the root *puri śete* - lying in the body, embodied), *kṣetrajña* (from *kṣetram jānāti* - one who knows the body, embodied self). Thus, it can be seen that the self in all these meanings differs from the usual notion of ego: what a person is, their identity, etc., with which one associates the self in ordinary understanding. While we cannot believe that Vedic literature, as it exists today, contains early thought pertaining to the question of personal identity, what we do have is fairly representative of the directions this inquiry took. More importantly, these meanings persisted and were standardized in the course of time, so that in the later schools of philosophy (*c*.200-600 AD), as well as in popular Hinduism, these were accepted as words that convey the idea of the self.

The inquiry in the Upaniṣads was mainly speculative. It had the dual purpose of finding the ultimate principle that was the basis of the universe and the true nature of the individual self. The first inquiry led to the postulation of Brahman (from root *bṛh* - to expand, burst forth) as the source behind the universe. This was the culmination of the trend set in hymns like *Ṛg Veda* 1.164.46, 10.81, 10.90, 10.129, where different ideas are expressed regarding the

ultimate source of the universe. This concept finally settled down with the notion of Brahman being described both as immanent in the cosmos (Chāndogya Upaniṣad 3.14.1, 7.25.2) and as transcending the same (Bṛhadāraṇyaka Upaniṣad 3.8).

The other inquiry was directed towards discovering the identity of the self by analysing the inner nature of the human being. Having arrived at the conclusion that the individual self cannot be identified with any one of the senses (both motor and cognitive), through a process of elimination (Kena Upaniṣad 3.4) the mind as being the self was also ruled out as it was obvious that all mental states had something other than the mind as their referent which was also constant. While this form of inquiry was a process from the gross to the subtle elements, another feature was the observation that the 'sense-of-I' (personal identity) was invariably associated with consciousness (self-awareness) and knowledge. This, combined with the persistence of the 'sense-of-I' in all the three states of waking, dreaming and deep sleep led to the postulation of the *ātman* being the inner self, which is the ultimate principle (Bṛhadāraṇyaka Upaniṣad 4.3 and 4).

There were other trends which were growing in the same period which would contribute to the enrichment of the concept of *ātman*. By the time of the Upaniṣads the concepts of *dharma* (from root *dhṛ* - to sustain, support, behave in a human way) and that of karma (from root *kṛ* - to act (ritually)) had evolved into metaphysical principles. The goals of life called *puruṣārthas* had also been formulated by this time as the pursuit of *dharma*, *artha* (economic goal constituting *dharma*), *kāma* (sensual fulfilment within *dharma*) and finally *mokṣa* (liberation from bondage, or to a state of one's true nature).

All these ideas working on the self meant that good karma will result in a good life on earth, while its opposite will lead to a bad life. Since one single life could not adequately explain the inequalities present in life, the same self came to be considered eternal, taking birth repeatedly after the fall of the body (death) until such time as it realizes the futility of this worldly existence (see Karma and rebirth, Indian conceptions of). The way to realize that was to overcome the ignorance of identifying the self with the body through experiencing the true nature of the self, either by following the path of knowledge, of disinterested action (action for its own sake without thinking of the result or reward), or the path of devotion. In the course of time these came to be the famous threefold paths of *jñāna mārga* (knowledge path), *karma mārga* (action path) and *bhakti mārga* (devotion path). Yoga also came to be recognized as a path by the time of the *Bhagavad Gītā* (*c*.200 BC). The state of liberation was called variously *mokṣa*, *apavarga*, *nirvāṇa*, *kaivalya*, *sāyujya* and so on.

2 The Upaniṣadic view

By pursuing a methodology that mainly combined perception, inference, experience and speculation the Upaniṣads reach a startling and bold conclusion. This was the identification of the ultimate truth underlying the universe called Brahman with the inner self of all beings called the *ātman*. It was the same *ātman* that was present in all living beings, the differences seen being attributed to the nature of the respective body it occupies (see Brahman). The journey that ended in this equation can be described in a twofold manner: one that approached the question in an objective, external direction; the other which turned its attention to the inner nature of oneself, or adopted a subjective approach.

The objective search went through the exercise of finding the ultimate principle that underlies the universe (*Ṛg Veda* 10.31.7). But significant to the *ātman-Brahman* equation is the tendency to find a correspondence between the individual and the universe in a 'micro-macro' paradigm that manifests itself very early in the period, for example, in the *Ṛg Veda* 10.90, 10.16, *Atharva Veda* 11.4, Aitareya Upaniṣad 1, Chāndogya Upaniṣad 3.16.1, 5.11-18. This came to be known as the affinity (*bandhutā*) theory. Side by side there was the tendency to assign the world an inferior status compared to the transcendent nature of Brahman (*Ṛg Veda* 10.129).

The subjective approach, on the other hand, analysed the inner person in a twofold manner. One was the approach from the gross to the subtle and the other was from the point of view of knowledge and the principle of consciousness. The first approach led to the elimination of all motor senses and the senses of knowledge as being the self (Kena Upaniṣad 3, 4). Even the mind was ruled out as the enduring self for it was obvious that all mental states referred to something other than themselves as a basis for those states and also this referent was a constant factor underlying all mental states, as in the Kaṭha Upaniṣad 2.2.1, 3.5, 3.10. and the Kena Upaniṣad 1.4.8. It was also observed that the self was always associated with any event of cognition.

Another interesting discovery was the fact of the persistence of the ‘sense-of-I’ in the three states of waking, dreaming and deep sleep. The deep sleep identity was explained by the fact that the person who gets up from such a slumber recognizes their own identity as the one who had that experience of sleep. As these three states were still within the realm of worldly existence, *ātman* was viewed as transcending these three states and reaching its pure form in a fourth stage which is identified with the state of freedom (Chāndogya Upaniṣad 8.6, Māṇḍūkya Upaniṣad 1).

The affinity phenomenon, combined with the immanent and transcendent nature of both *ātman* and Brahman, made it easy to equate the one with the other. Thus by the time of the Upaniṣads the *ātman* was established as the self in any living being, it was of the nature of pure consciousness, it was identified with Brahman very often denoted by the word *paramātman* (highest self) and was of the nature of both immanence and transcendence (Bṛhadāraṇyaka Upaniṣad 2.4.14, Taittirīya Upaniṣad 2.1-5). As for the question of whether this *ātman* can be known like any other event in knowledge, the Upaniṣads seem to suggest only an intuitive realization of the self which is different from knowledge understood in everyday life (Kena Upaniṣad 2.2, Kaṭha Upaniṣad 2.23).

3 *Dharma*, karma, human goals and transmigration

There were many other ideas which reached maturity during the time of the Upaniṣads and which led to the theory of the permanent nature of the *ātman*. The Brahman- *ātman* equation and their status as the final truth in an interchangeable manner posed a problem for the philosopher; if something is existent in an absolute sense it cannot be negated at any time or in any sense. Thus, in order to preserve the immutable nature of *ātman* it was conceived as being a permanent entity, existing even after the fall of the body (Māṇḍūkya Upaniṣad 4.40, Kaṭha Upaniṣad 2.18, *Bhagavad Gītā* 2.16).

The concepts of *dharma* and karma had evolved into metaphysical principles that held sway over the lives of individual selves on this earth. It is not possible to trace all the nuances of meaning that *dharma* went through before it settled down to mean virtue, merit, good conduct and also to be raised to the status of the first of the goals of human beings. These goals were four in number, called *dharma*, *artha* (pursuit of economic ends within *dharma*), *kāma* (legitimate sensual pleasure within *dharma*) and *mokṣa* (liberation from repeated births to deaths).

Karma meanwhile had also grown into a fully fledged theory out of the necessity to explain inequalities seen in the world. It was a theory of ethics relating one’s life on earth to the kind of deeds one had done in past lives (Kaṭha Upaniṣad 2.2.7). In this way, since the inexplicable details of a single life could not be explained, the self came to be accepted as a permanent entity that transmigrates from one birth to another until it realizes its true nature. This realization could come through knowledge, disinterested action or devotion. Later Yoga also came to be recognized as a means to the final goal.

We now get a concept of the self which is eternal, connected with a body due to its own good or bad deeds, capable of realizing its true nature by following the spiritual path best suited to itself, which finally escapes the circle of births and deaths attaining *mokṣa*. The nature of *mokṣa* that the self attains will depend on the kind of ontological status assigned to the final truth in each philosophical system. Some retain a theistic, cosmic view of the ultimate while others favour a monistic, acosmic perception. While the goal of *mokṣa* may be defined variously depending on the nature of Brahman, the self is viewed in the same way in practically all schools of Hindu thought.

4 Six schools of Hindu thought

The six schools of Hindu thought are collectively called the *āstikadarśanas*. *Āstika* stands for that which does not reject the authority of Vedic literature and *darśana* literally means vision. Thus, *darśana* is the equivalent of philosophy in the Hindu context. It also indicates that philosophy does not end with just an intellectual understanding of what the ‘self’ is, but it culminates in ‘seeing it’ or ‘becoming it’.

The six *darśanas* are Nyāya, Vaiśeṣika, Sāōkhya, Yoga, Mīmāṃsāand Vedānta. While each of these systems had an independent beginning, some came to be designated jointly as twin systems because of certain affinities in their metaphysical theories. Thus, after the grouping, the six systems are referred to as Nyāya-Vaiśeṣika, Sāōkhya-Yoga and Mīmāṃsā-Vedānta in the philosophical treatment of the schools. Each of these developed its own extensive theories regarding both ontological and epistemological categories, but all were in agreement regarding the eternal

nature of the individual self and in its ultimate liberation from births and deaths, however they may differ in detail. These schools can also be viewed as representing different philosophical approaches to the understanding of the ultimate categories. They range from the most realistic (Nyāya-Vaiśeṣika) to the most idealistic (Advaita Vedānta) in the way they approach the theory of the *ātman*.

5 Nyāya-Vaiśeṣika

As the name signifies Nyāya (reasoning) lays emphasis on the method of critical reasoning. Vaiśeṣika, on the other hand, is derived from the word for particularity (*viśeṣa*) which is one of its ultimate categories. It conveys a sense of differentiation even between things which cannot be otherwise differentiated. Among the six schools Nyāya-Vaiśeṣika is the most realistic as it believes in the independent existence of objects in the world. All objects of experience are divided into seven classes in the Vaiśeṣika: one of them is known as substance (*dravya*). We will pay attention only to the substances, of which there are nine, one of which is *ātman*; the other eight are earth, water, light, air, ether, space, time and the mind. The Nyāya has a scheme of sixteen ultimate philosophical topics and the seven of Vaiśeṣika come under its second topic called knowable things (*prameya*) (see Ontology in Indian philosophy).

Since the treatment of *ātman* is similar in both Nyāya and Vaiśeṣika, henceforth it will be treated as a single school for purposes of the *ātman* problem. The *ātman* is unique, eternal, all-pervading and there are as many selves as there are bodies associated with them. Consciousness is not intrinsic to *ātman*, but it is only one of the many qualities that the self has. It is not only an essential quality but also an adventitious attribute along with desire, volition, pleasure, pain, love, aversion, virtue and vice.

The system is in agreement with the general theory of the bondage of the *ātman* in the round of births and deaths. The reason for this state is lack of true knowledge of the self as distinct from all other things, which is the reason for pain. When correct knowledge dawns through study of the sacred books and by the practice of Yoga, there is the destruction of ignorance and the achievement of the goal of liberation. The fact that the self does not also have the attribute of consciousness in liberation means that the self is not conscious of its own freedom. Although a Supreme self known as the Lord (*Īśvara*) is admitted in the school, it is restricted to being the efficient cause of the world and does not extend to the sphere of liberation of the individual self. Nyāya and Vaiśeṣika do not believe in liberation while still in an embodied state as some of the other systems do (see Nyāya-Vaiśeṣika).

6 Sāōkhya-Yoga

The school of Sāōkhya-Yoga recognizes two ultimate ontological categories called *prakṛti* (material nature) and *puruṣa* (personal self). The selves are also many as in Nyāya and Vaiśeṣika. While Sāōkhya and Yoga agree in this classification, Yoga also believes in God, who is described as a unique person different from both material nature and the personal selves in bondage; God has never been subject to the bondage of births and deaths (see God, Indian conceptions of §4). The evolution of the universe takes place from material nature, which is composed of three material qualities. Material nature is perpetually in motion and replicates itself when there is an equilibrium of the constituent qualities. When this balance is upset evolution is set in motion and leads to the unfolding of the different principles. In Sāōkhya the basis for the evolution to start is the presence of the *puruṣa*: it is not clear whether one self or many selves are intended here, but some kind of connection with karma seems to be suggested. It is this difficulty that Yoga tries to overcome by postulating a God who effects the association of material nature with the unseen karma of selves and starts the process of evolution. However, the concept of a Supreme self over and above the other selves seems more a practical necessity and does not serve any philosophical purpose.

In Sāōkhya-Yoga the self is characterized by pure consciousness, unlike in Nyāya and Vaiśeṣika, where consciousness is only one of the attributes of the soul. It is the false identity of the *puruṣa* with material nature (which in its psychological and bodily effects are represented by intellect, ego-sense, mind, five motor senses, five senses of knowing, five subtle elements, the five gross elements of earth, water, fire, wind and ether), which is called ignorance that causes bondage to the self. This false identification comes about due to the capacity of the intellect to reflect *puruṣa* onto itself as a mirror, which then imagines itself to be the experiencer of all that happens. This false knowledge has to be rectified by true knowledge. This is the stage when discriminate discernment as to the true nature of *puruṣa* and material nature dawns. There is a difference in the way this stage is described in Sāōkhya and Yoga, but both generally agree to it in essence.

It is perhaps in the means that one adopts for liberation that the two still retain their distinctiveness. The Sāōkhya does not elaborate on it and mentions only meditation on the difference between material nature and *puruṣa* as the means (*Sāōkhyakārikā* 64). This resembles the Nyāya and Vaiśeṣika approach through study, reflection and applied meditation. On the other hand, Yoga lays down an elaborate plan of psychological preparation which will result in isolating *puruṣa* from its entanglement with material nature through an eightfold path of Yoga.

While Sāōkhya describes this state of liberation as *apavarga* (escape from pain), Yoga calls it *kaivalya* (the self abiding alone in its own nature). Both Sāōkhya and Yoga believe that this liberation can be attained while still living in the world. The second liberation is that which comes on the fall of the body and is termed *videhamukti* (see Sāōkhya).

7 Mīmāṃsā and Vedānta

These two systems can be discussed together as they have some common understanding of the Vedas, although they differ in their basic philosophy. Of all the six systems, the Mīmāṃsā assigns a paramount position to the ritualistic portion of the Vedas (*brāhmaṇas*). Ritual is the pivot around which its ontology and epistemology are built. As it accords an inferior status to the Upaniṣads (that come at the end of the Veda and are known as Vedānta), it is called Pūrva Mīmāṃsā (reflection on the earlier portion of the Veda). Opposed to this is the Uttara Mīmāṃsā, for whom the Upaniṣads are the quintessence of philosophy.

The selves in Mīmāṃsā are eternal, all-pervasive, have knowledge as their attribute, are many and are completely under the control of ritualistic activity (karma), which is also at the back of the formation of the world of objects. As karma is self-sufficient to explain both the world and the selves there is no belief in the existence of God. It is thus a realistic school which postulates the continuation of the self after death in another world until it returns to the earth after reaping the fruit of its ritual acts in the previous life.

Virtue (*dharma*) and vice (*adharma*) are called together *apūrva* (something never known before) and are the result of ritual action. *Dharma* is defined in the school as an injunction to perform a deed (sacrifice), and *adharma* is its opposite. One learns of what is *dharma* and *adharma* from the Vedas. Karma in this scheme is described mainly as threefold: first, done to obtain some desired result, like the gaining of heaven after death; second, prohibited, as its indulgence will lead to undesirable results; third, mandatory, the performance of which is for its own sake (see Duty and virtue, Indian conceptions of).

If one then acts as instructed by the Veda, the highest result of liberation (which in its earlier stages was equivalent to attaining heaven through *dharma*, or even equivalent *dharma* per se) would be accomplished. This is now understood, like all the other systems, as an end to the round of births and deaths for the individual self and a cessation of its relation to the world. In liberation all attributes of the self, including that of consciousness, also disappear. Thus it resembles Nyāya-Vaiśeṣika in the state of liberation, except that it retains the potential to manifest these qualities. However, once liberation is achieved, according to the Mīmāṃsāview, there will be no need for the self to manifest such attributes as consciousness. Again as in Nyāya-Vaiśeṣika and Sāōkhya-Yoga, the state of liberation is described negatively as *apavarga*, an escape from worldly existence (*saṃsāra*). As in Nyāya-Vaiśeṣika, liberation is also only obtained on the fall of the body and there is no belief in being liberated while still alive (see Mīmāṃsā).

Vedānta is based on the three works the *Brahmasūtra*, the Upaniṣads and the *Bhagavad Gītā*. These three together are known as the Three Texts and at least six schools of Vedānta, along with many variations, have sprung up, divided according to the way the Three Texts have been interpreted. While these schools differ in the ultimate ontological categories and in the relationship of the ultimate being to the individual self, they do not differ substantially in their understanding of the nature of the self.

Since Advaita is the earliest of the Vedānta schools, we can start with the nature of the self given in it. This system pursues relentlessly the logic of monism in the Upaniṣads and maintains the nondual nature of the ultimate truth called Brahman, which is identified with *ātman* (individual self) and is the only reality, all others including the world being explained as a superimposition on Brahman due to ignorance. Brahman is intrinsically without attributes, but it is of the essence of existence, consciousness, and bliss, and it is infinite (Taittirīya Upaniṣad 2.1). Even God is only a superimposition and is brought in to make sense of the world of objects. The individual self, which in all other systems is an ultimate entity, is here a complex of Brahman characterized as an eternal witness

and the objective internal organ (see Monism, Indian).

This complex called the living soul (*jīva*) serves to explain among other things the notion of ego that is superimposed on the pure witness. The living soul is caught up in the world of births and deaths due to beginningless karma and identifies itself with the body and the senses. Since the self is really Brahman, only in association with the internal organ, liberation is not some state to be achieved but is to be realized in experience. The obstacle of ignorance has to be removed and this makes Advaita assign paramount importance to knowledge as the only means to liberation.

Such knowledge, which results in an identity experience with Brahman, can only be of a rare kind. Although the direct means is knowledge, there is a preliminary training which strengthens detachment from the world and cultivates a strong desire for liberation. Then comes the rigorous study under a *guru*, someone who has realized the truth of the Upaniṣads. Next there is the following of the instructions introspectively through reasoning and finally the aspirant must engage in constant meditation on the truth reasoned out. Such a course will result in an immediate experience of the identity with Brahman in the form *aham brahma asmi* ('I am Brahman' (Bṛhadāraṇyaka Upaniṣad 1.4.10)). This is possible while still in the body. When the body falls, the self, being disassociated from ignorance, stays as Brahman.

The other Vedānta schools consider the self not in the complex way that Advaita does; they essentially differ in recognizing a personal god as the ultimate entity; the self is eternal, characterized by knowledge and bliss in all these schools; in addition the Dvaita school also believes that each living soul is different from every other. All the schools believe in the bondage of the selves due to karma and ignorance; they are all in agreement about devotion to God being the highest means to liberation. But the liberation is one in which duality persists; they also do not believe in liberation during life, as the ontology assumes attainment of liberation in another world, in which one's God resides (see Vedānta).

Self-control

A human person or self possesses powers that can come into conflict. Reason may have to struggle to overcome contrary desire. Self-control may be characterized as the ability to regulate or resolve such conflict correctly. A well-ordered self has self-control; a disordered self lacks it. When an agent lacks self-control, inner conflict often results in the victory of evil over good. Philosophers such as Plato, Aristotle, and Kant have painted portraits of the disordered self. They are alike in portraying its actions as stemming from appetites or desires that are not properly ruled by some 'higher part' of the self. These philosophers have also proposed accounts of the well-ordered self. They are alike in depicting it as a self in which a part of the self connected with reason or wisdom governs a 'lower part' associated with appetites or desires.

1 The disordered self

According to Plato, a disordered self is a soul whose parts or components are in conflict. The *Phaedrus* likens the soul to the union of powers in a pair of horses and their charioteer. One of the horses struggles against control by the charioteer. If the rebellion were to succeed, the soul would do something evil the charioteer does not want to do. In Plato's *Republic*, the soul is divided into rational, spirited and appetitive parts. A struggle for control between the rational part and the spirited part or the appetitive part occurs in a disordered self.

For Aristotle, a disordered self is an incontinent or akratic self (*Nicomachean Ethics*). It suffers from weakness of will or *akrasia* (see Akrasia). Suppose some people on a diet ought not to eat sweets. Knowing this, when they perceive that this piece of cake is sweet, their practical reasoning should move them to reject it. But if they are incontinent, an appetite for pleasure may make another line of reasoning more salient. In the presence of an appetite for pleasures of taste, if they believe that all sweet things are pleasant, their perception that the piece of cake is sweet may move them to eat it. Though they are aware that they ought not to eat sweets, they eat the cake because their reasoning is unduly influenced by an appetite.

Aristotle recognized two kinds of incontinence: the weak deliberate about what to do but fail, on account of their passions, to stand by their conclusions; the impetuous fail to deliberate, in some cases because they are too quick to make up their minds and in others because their appetites are too strong. Both the weak and the impetuous are apt to be aware of the general practical principle that should determine their actions. Hence, as Aristotle observes, the incontinent are likely to repent, acknowledging in retrospect that they have done something they should not have done.

According to Kant (1793), the disordered self suffers from a radical evil in human nature. Influenced by the Christian doctrine of original sin, Kant believed that there is a propensity to evil deep in all of us. We bring it upon ourselves by freely adopting a policy for acting that does not respect the proper order of the incentives for the will. The incentives provided by our inclinations or sensuous desires always ought to be subordinated to the incentive of respect for the moral law in the maxims on which we act. A policy that does not respect this order manifests itself in particular cases in the frailty, impurity, or wickedness of the human heart. The frail are those in whom the incentive of respect for moral law proves in practice to be weaker than their inclinations; they want to act morally but do not do so. The impure are those by whom dutiful actions are done not purely for duty's sake; they act in accord with the moral law but from mixed motives because respect for the law is not a sufficient incentive for their wills. The wicked neglect the incentive of respect for moral law altogether; even when they act in accord with the moral law, they do the right thing for the wrong reasons and so are corrupt in their cast of mind (see Sin §3).

These three pictures of the disordered self have something in common. They portray its actions as flowing from appetites or desires that have not been subordinated properly to the rule of some higher part or aspect of the self. Bad or evil action results when the self allows unruly appetites or desires to get out of hand.

2 The well-ordered self

For Plato, the remedy for lack of self-control consists of establishing the mastery of the rational part of the soul and rendering docile the other two parts. The rational part of the soul is described in the *Republic* as the ruling principle: the self is well-ordered when reason's two subjects are agreed that reason ought to rule and so do not rebel against it.

As Aristotle sees it, practical wisdom determines the right rule for action. Since an incontinent person is one who allows bodily appetites to move them to act contrary to the right rule, a continent person will be one who possesses such appetites but does not allow them to have such motivating force. Aristotle tells us that the continent person does nothing contrary to the rule for the sake of the bodily pleasures. A person who is merely continent will have bad appetites and will feel pleasure contrary to the right rule but not be led by it to act contrary to the rule. Hence, Aristotle's initial remedy for lack of self-control is continence. A continent self is well-ordered because it has self-control with respect to action. For Aristotle, however, merely being continent is not the ideal state of the self; it is better to be temperate. Like the continent agent, the temperate agent does nothing contrary to the rule for the sake of bodily pleasures. But the temperate agent does not have bad appetites and does not feel pleasure contrary to the right rule. In such a self not only actions but also appetites and feelings are in accord with the rules specified by practical wisdom. Thus, Aristotle's ultimate remedy for lack of self-control is the virtue of temperance. Yet it is doubtful that temperate people should be thought of as having self-control. Lacking bad appetites, they seem to have nothing unruly within them that needs to be kept under control. It appears, then, that a person who has self-control is one who achieves continence but falls short of temperance (see Virtues and vices §§2-3).

According to Kant, the remedy for radical evil in human nature that manifests itself in frailty, impurity, and wickedness is a moral revolution in character in which one freely adopts a policy for acting that respects the proper order of incentives for the will. There is in all of us a capacity for respect for the moral law to serve by itself as a sufficient incentive for the will, and this capacity is not destroyed by our propensity to evil. Kant thought it can be restored to its original purity if we reverse, in a single unchangeable decision, the evil policy of not always subordinating the incentives of inclination or sensuous desire to the incentive of respect for the law. Kant did not profess to know how such radical character change is possible. He was confident, however, that we can bring it about because he was persuaded both that it is our duty to do so and that whatever we ought to do we can do. And such a moral revolution will, he thinks, set us on a path of continual progress from bad to better in our actions. So the Kantian remedy for lack of self-control is a revolution in character that results in respect for the moral law, which is the legislation of our own practical reason, being restored to its dominant place in the hierarchy of our incentives for action.

These three accounts of self-control resemble one another to a considerable extent. In all of them, self-control consists of a 'higher part' of the self, associated with reason or wisdom, governing a 'lower part' of the self, associated with bodily appetite, sensuous desires, passions or feelings. Though such rationalistic accounts of self-control have been dominant in philosophy, they have not escaped criticism. Few philosophers would consider unbridled wantonness or self-indulgence virtuous. But many contemporary feminists, for example, are apt to suspect gender bias in the thought of the self as a monarchy ruled by reason. Such critics are motivated to construct more democratic models of the well-ordered self in which parts of the self cooperate, reason need not always be in control, and the cultivation and expression of feeling are valued (see Feminist ethics).

Self-cultivation in Chinese philosophy

Chinese philosophy may be viewed as disciplined reflections on the insights of self-cultivation. Etienne Balazs asserted that all Chinese philosophy is social philosophy and that, even if Chinese thinkers dwell upon metaphysical speculation, they will sooner or later return to the practical issues of the world here and now. This concern for the concreteness of the life-world gives the impression that the social dimension of the human condition features so prominently in the Chinese world of thought that the idea of the group takes precedence over conceptions of the individual self. The anthropological studies that contrast the Chinese sense of shame with the Western sense of guilt further enhance the impression that external social approval, rather than internal psychological sanction, defines the moral fabric of Chinese society. The prevalent sociological literature on the mechanism of 'saving face' as a key to understanding Chinese interpersonal relationships also stresses the centrality of external conditioning in Chinese ethics.

If we follow this line of thinking, it is easy to assume that Chinese philosophers are preoccupied with neither the transcendent referent nor the inner psyche. They are not particularly interested in questions of ultimate reality such as the creator, the origin of the cosmos or the existence of God. Nor are they engrossed in problems of the mind such as consciousness, self-identity or moral choice. Indeed, Chinese philosophy as social philosophy seems exclusively immersed in issues of correct behaviour, familial harmony, political order and world peace. Even strands of thought that emphasize the aesthetic experience of the self are all intimately bound up with the highly ritualized world of human-relatedness. Actually the spirit of spontaneity, as a liberation from social constraints, should be appreciated in terms of a conscious reflection on and critique of society and thus inherently sociological.

However, this widely held opinion of Chinese philosophy is seriously flawed. While it offers a common-sense picture of where the strength of Chinese thought lies, it does not address the underlying reasons or the actual processes that define the main trajectory of the Chinese modes of thinking. Wing-tsit Chan suggests a more comprehensive characterization of Chinese philosophy as humanism: 'not the humanism that denies or slights a Supreme Power, but one that professes the unity of man and Heaven' (Chan 1963: 3).

It is crucial to note that 'humanism' so conceived is diametrically opposed to secular humanism as a distinctive feature of the Enlightenment mentality of the modern West. Western humanism emerged as a thorough critique of spiritualism and a radical departure from naturalism, or a sense of affinity with nature; it was the result of secularization. Chinese humanism, on the other hand, tends to incorporate the spiritual and naturalist dimensions in a comprehensive and integrated vision of the nature and function of humanity in the cosmos.

The advantage of characterizing Chinese philosophy as humanistic rather than sociological is to open the possibility of allowing aesthetic, religious and metaphysical as well as ethical, historical and political perspectives to shape the contours of the Chinese reflective mind. This synthetic approach better captures the spirit of Chinese thought because it was historical and social change, rather than speculation, which was instrumental in the outgrowth of humanism as a defining characteristic of Chinese philosophy.

1 Chinese philosophy: the beginnings

The advent of Chinese philosophy was not marked by rupture from a mythic, religious world of shamanistic panpsychism to 'rational' reflection, but by a moral discourse on the interplay between the Mandate of Heaven and human virtue. As the pre-Confucian *Shijing (Book of Odes)* notes, the establishment of the Zhou civilization in twelfth century BC was the result of virtuous deeds:

> Don't you mind your ancestors!
> Cultivate your virtue.
> Always strive to be in harmony with Heaven's Mandate.
> Seek for yourselves the many blessings.

(*Shijing*, in Chan 1963: 7)

The idea of cultivating virtue as a human endeavour to harmonize with Heaven's Mandate and to seek blessings

provides a root metaphor for self-cultivation.

2 Philosophy as a spiritual quest: Confucius

This lack of differentiation between religious commitment and intellectual reflection, as implied in this idea of self-cultivation, has profound implications for our understanding of the nature of Chinese philosophy, which is a spiritual discipline directed toward human flourishing. The realms of abstract theory, devoid of significance for practical daily living, are rejected as the proper domain for the life of the mind. Indeed, the insistence that thinking must be grounded in the lived concreteness of the human condition is based on the 'anthropocosmic' vision that human beings, through self-effort, can fully realize their nature as co-creators of the cosmic process.

Confucius' pithy account of his life history is a paradigmatic example that self-cultivation is pivotal in each stage of his learning to be human:

> At fifteen, I set my heart on learning.
> At thirty, I took my stand.
> At forty, I came to be free from doubts.
> At fifty, I knew the Decree [Mandate] of Heaven.
> At sixty, my ear was attuned.
> At seventy, I followed my heart's desire, without overstepping the line.

(*Analects* 2.4)

The very fact that Confucius located the beginning of his spiritual journey at fifteen indicates the conscious choice to shape the direction of his life through learning as awakening, and marks the definitive boundary between givenness and wilful transformation. Meaningful life begins when one has made a conscious choice to learn to become human through self-effort. The ability to 'plant one's feet firmly on the ground' and find a proper niche in society implies that the inherently personal undertaking of self-cultivation necessarily involves a social dimension. However, despite the commitment that learning as awakening entails the internalization of social norms in every facet of ordinary daily living, the inner strength of self-knowledge does not depend upon standards superimposed from the outside. Indeed, when one is free from 'perplexities', there is a depth of self-awareness which engenders a profound sense of direction.

The transcendent dimension at the age of fifty, instead of a departure from the 'humanist' quest for self-realization, offers a new insight on the human condition. The significance of the evocation of the Mandate of Heaven is twofold: on the one hand, it indicates a critical, if not tragic, recognition of the structural limitations inevitably imposed by aging; at the same time, it also symbolizes a transcendental breakthrough in self-awareness. The former shows that since we are merely human; we cannot but come to terms with our mortality. As Confucius said, to know what we do not know is wisdom; we may analogize that to accept fully the responsibility for what we cannot do is a sign of courage. This 'transcendental breakthrough', then, implies that despite our conditionality, what we do and what we become as humans has cosmological significance.

The deliberate choice of aural rather than visual perception as a way of depicting Confucius' stage of self-cultivation at sixty is profoundly meaningful. The art of listening requires the calmness of the heart and the patience to receive all the messages without prejudging any of them. As an accomplished listener, the dynamic temporality broadens and deepens one's awareness of the outside world without affecting inner tranquillity. The harmony between what one does out of natural impulse and what one ought to do as dictated by moral obligations is, therefore, a further refinement on training the ear to be docile. Within this context, the spirit of spontaneity and freedom that Confucius experienced at seventy, as the result of decades of continuous self-cultivation, has become a standard of inspiration in Chinese moral philosophy.

While Confucius' life history is itself a lesson of self-cultivation through exemplary teaching, it is not meant to be a rigid model for human flourishing. Confucius' attainments depended so much on a confluence of conditions involving economic circumstances, social class, political situation and cultural milieu that it is unique and unrepeatable (see Confucius). Confucian followers rejected the idea of imitating Confucius but insisted upon the relevance of his example for emulation (see Confucian philosophy, Chinese). The best way to emulate Confucius is to practise his way of learning to be human through our own self-cultivation. A commitment to internalize the

central values of his teachings and integrate them into our daily life is required. However, this does not mean that we have to suspend our rational thinking and critical judgment in order to embrace the Confucian project. The fusion of intellectual inquiry and spiritual transformation suggests that the philosophy of self-cultivation is predicated on an experiential understanding of how it actually works; acceptance of any unexamined dogmas or implicit doctrines is not a precondition.

In response to the query, ‘is there a single saying that one can act upon all day and every day?’ Confucius said, ‘Perhaps the saying about reciprocity: "Never do to others what you would not want them to do to you".’ What is the status of this ‘golden rule’ in Confucian moral philosophy? On the surface, it seems to be a dogma and a doctrine, yet, as presented, it does not have the force of ‘thou shall not do otherwise’. It is an observation, a suggestion, a recommendation. The implicit message is: put this ‘rule’ into practice in your ordinary interpersonal relationships, and see how it actually works. Assuming that this emphasis on considerateness is sometimes unworkable because the anticipated sympathetic response is absent, should the practice be continued? As concrete practice rather than abstract principle, a realistic assessment of the situation is critical in the application of the Confucian golden rule. When Confucius was asked about the merit of repaying malice with kindness, instead of encouraging the student to cultivate what may be called a higher morality of considerateness, Confucius retorted, how are we to repay kindness? If our reciprocal response to malice is kindness, we may have difficulty responding appropriately to kindness. The recommendation that we repay malice with justice and kindness with kindness is to encourage attention to the specificity of the situation in formulating a measured response.

However, it is mistaken to characterize Confucian self-cultivation as a form of situational ethics. As a virtue-centred moral philosophy, an overriding concern is the cultivation of a personality through character-building that will be able to respond to all situations with dignity and openness:

> The profound persons have nine areas for which they are mindful. In seeing they are mindful of seeing clearly; in hearing they are mindful of hearing distinctly; in looks they are mindful of being good-natured; in their manners of being reverential; in their words of being trustworthy; in their works of being diligent. When in doubt they are mindful of asking for information; when angry they are mindful of the consequences, and when they see a chance for gain, they are mindful of whether the pursuit of it would be consonant with rightness.
>
> (*Analects* 16.10)

Concrete situations provide the opportunity to put general principles, such as the golden rule, into practice, but self-cultivation as a way of learning to be human takes as its primary purpose the fostering of balanced personalities:

> When there is a preponderance of native substance over acquired refinement, the result will be churlishness. When there is a preponderance of acquired refinement over native substance, the result will be pedantry. Only a well-balanced admixture of these two will result in gentlemanliness.
>
> (*Analects* 6.18)

It should be noted that the self in Confucian self-cultivation is not an isolated or even isolatable individual, but a centre of relationships. As a centre, there is a unique configuration of social roles evolving around the autonomous and independent self. The self as an end, rather than a means, can never be reduced to these roles. Confucius’ injunction that the profound person is not a vehicle clearly shows that the dignity of the person cannot be fully appreciated by referring merely to their role and function in society. The paradox is of course that each social role (that is, parent, child, teacher, student, patron, client, employer, employee, farmer, worker, merchant, business executive, lawyer, doctor, journalist, artist, writer or computer programmer) provides an opportunity for self-realization. As a centre of relationships, the self is enriched and empowered by a continuous interaction and interchange with other selves. Nevertheless, balanced personalities are not simply well-adjusted to the vicissitudes of the external environment; an inner core of self-knowledge serves as a spring of rich spiritual resources.

3 Ultimate justification: Mencius

The great contribution that Mencius made to the Confucian project is precisely locating this inner core in human nature:

> A profound person [gentleman] steeps himself in the Way because he wishes to find it in himself. When he

> finds it in himself, he will be at ease in it; when he is at ease in it, he can draw deeply upon it; when he can draw deeply upon it, he finds its source wherever he turns. That is why a profound person wishes to find the Way in himself.
>
> (*Mengzi* 4B14)

There is a paradox in the assertion that profound persons, intent on finding the Way in themselves, steep themselves in the Way. If the Way is already in us, all we need to do is to find it through introspective self-examination. Indeed, Mencius seems to believe that is the case:

> All the myriad things are present in me. There is no greater joy for me than to find, on self-examination, that I am true to myself. Try your best to treat others as you would wish to be treated yourself, and you will find that this is the shortest way to humanity.
>
> (*Mengzi* 7A4)

However, by steeping ourselves in the Way, we are enjoined to make a conscious effort to realize that, if we follow our original nature, we are intrinsically congenial to the Way. By implication, since we are not necessarily what we ought to be, we may easily mistake that part of us which is contrary to the Way as the true self. The art of self-cultivation, then, is to know the difference and to act accordingly. Mencius straightforwardly articulates what he observes as the central *Problematik* in self-cultivation:

> When our senses of sight and hearing are used without thought and thus become obscured by material things, the material things act on the material sense and lead them astray. That is all. The function of the mind-and-heart is to think. If we think, we will get the principles of things. If we do not think, we will not get them. This is what Heaven has given us. If we first build upon the ‘great body’ of our nature, then the ‘small body’ cannot overcome it. It is this which makes human beings great.
>
> (*Mengzi* 6A15)

Although we are not what we ought to be, the process by which we learn to become so can be initiated from the very structure of what we are here and now. The assumptive reason is that the ultimate justification for self-cultivation lies in the feeling, willing, knowing, and sensing capacities of the heart-and-mind. As long as our heart-and-mind can feel the suffering of others, there is the authentic possibility of self-cultivation. Human beings so defined are primarily sentient beings. Our sensitivity, which includes rationality, enables us to experience directly the sympathetic and reciprocal resonances with other human beings and the world at large.

Yet, it is necessary that we know the difference between the ‘great body’ and the ‘small body’ in our nature. We must not allow our desires, especially appetite and sex, to dominate, or we will be obsessed with the demands of the small body. As a result, our behaviour can be easily defined in terms of the rules of the game common to all animals: survival and procreation. On the other hand, if we cultivate our great body in order to realize that ‘all the myriad things are present in me’, the potential for our interconnectedness is immense. Mencius’ art of nourishing the flood-like vital energy addresses this in seemingly mythical terms:

> [The flood-like vital energy] is the sort of vital energy which is utmost in vastness and utmost in strength. If through uprightness you nourish it and do not interfere with it, it fills the space between heaven and earth. It is the sort of vital energy which matches rightness with the Way. Without these it starves. It is generated by the accumulation of right deeds, and is not the sporadic right deeds that one might make a grab at. If anything in conduct is dissatisfying of the heart, it starves…. You must work at it and never let it out of your mind. At the same time, while you must not let it out of your mind, you must not forcibly help it either.
>
> (*Mengzi* 2A2)

Viewed from this perspective, Mencius’ thesis that human nature is good provides an ultimate justification for self-cultivation. The reason that we can cultivate ourselves is because the feeling, willing, knowing and sensing capacities of the heart-and-mind are inherent in our nature (see Xin (heart-and-mind)). Virtues of humanity, rightness, wisdom and propriety can be cultivated by appealing directly to the basic manifestations of human sensitivity: sympathy, empathy, the feeling of shame and dislike, the ability to know the difference between right and wrong and a sense of appropriateness.

4 Cultural transformation: Xunzi

While Xunzi, the great Confucian thinker of the third century BC, shares Mencius' vision that the human condition is improvable through self-effort and that moral education is absolutely necessary for the maintenance of social order, he doubts that human nature will automatically generate the creative process for human flourishing. He insists that the coercive power of the law, the influence of ritual and music, the authority of the ruler, the guidance of the teacher, and the enduring presence of good customs are all necessary for the harmonious functioning of society. His justification for self-cultivation is twofold: it is sociologically necessary on the one hand, and psychologically and epistemologically possible on the other.

Xunzi subscribes to an evolutionary theory of the advent of the human species with particular emphasis on its sociality. He observes that whereas all modalities of being have vital energy, plants have life and animals have consciousness, human beings alone possess rightness. A distinctive feature of the human sense of rightness is the ability to know the need and the intelligence to design the structure to organize human communities for survival and flourishing. Self-cultivation is central to the stability and solidarity of any human community. Human desires are numerous, but the material goods to satisfy them are limited. If desires are not properly channelled, social order cannot be maintained. Although coercive measures from the outside are necessary, in the long run the surest way is still moral self-cultivation. To be sure, human nature suffused with the passions of appetite, sex and aggression cannot in itself generate the mechanism for the development of pro-social sentiments, but the cognitive function of the mind has the capacity to make distinctions and intelligent choices.

Xunzi compares the mind to a pan of water: 'If you guide it with reason, nourish it with clarity, and do not allow external objects to unbalance it, then it will be capable of determining right and wrong and of resolving doubts' (*Xunzi*, in Liang 1996: 222). Understandably, an important concern of Xunzi's moral education is to free the mind from obsessions:

> What are the sources of obsession? One may be obsessed by desires or hates, by the beginning of an affair or the end, by the far away or close by, by breadth of knowledge or by shallowness, by the past or by the present. When one makes distinctions among myriad beings of creation, these distinctions all become potential sources of obsession. This is the danger in the use of the mind which is common to all human beings.
>
> (*Xunzi*, in Liang 1996: 222)

However, despite the mind's vulnerability, three distinctive qualities it possesses enable it to save humanity from self-destruction: emptiness, oneness and tranquillity.

The mind's receptivity is inexhaustible; no matter how much information it receives, there is always room for new. The emptiness of the mind offers a great capacity for learning. Xunzi believes that although human beings, as compared with other animals, are weak in physical strength, through learning they can be socialized to become the most intelligent. The mind also has the synthetic power to integrate fragmented ideas into a coherent pattern, and can do so without losing sight of its own inner identity. Similarly, while the mind responds dynamically to external stimuli, it can always maintain its internal tranquillity. These qualities enable the mind to exercise its cognitive function to control the passions of human nature.

Consequently, what Xunzi recommends as the central task of self-cultivation is to use the mind to govern human nature. Specifically, he recognizes the necessity of artfully constructed cultural forms to help the mind do this work. Law, ritual, music, norms and customs are all critically important in helping the mind to transform human passions so that their destructive influence on society can be minimized. Both Mencius and Xunzi see the need to control desires. They do not advocate asceticism, but they are fully aware that the best way to nourish the mind is to make desires few.

5 The root for human flourishing

The centrality of self-cultivation in classical Confucian humanism is captured in a pithy statement in the *Daxue (Great Learning)*:

> From the Son of Heaven on down to the common people, all must regard cultivation of the personal life as the root. There is never a case where the root is in disorder and yet the branches are in order. There has never been a case that what is treated with great importance becomes a matter of slight importance or what is treated with

> slight importance becomes a matter of great importance.
>
> (*Daxue* 1)

It is profoundly significant that the root and importance of self-cultivation is extended to the family, state and the world. It is not only a subject in moral education of the young but also the major concern of the body politic as a whole:

> The ancients who wished to manifest their clear character to the world would first bring order to the states. Those who wished to bring order to their states would first regulate their families. Those who wished to regulate their families would first cultivate their personal lives. Those who wished to cultivate their personal lives would first rectify their minds. Those who wished to rectify their minds would first make their wills sincere. Those who wished to make their wills sincere would first extend their knowledge. The extension of knowledge consists in the investigations of things.
>
> (*Daxue* 1)

Self-cultivation so conceived occupies a pivotal position in the link between the self and the community mediated by a variety of political, social and cultural institutions. At the personal level, it involves a complex process of empirical studies and mental disciplines. In terms of the whole project of human flourishing, it serves as the foundation of stable families, ordered states and a peaceful world.

The Confucians may have been particularly concerned about the social and political implications of self-cultivation, but self-cultivation features so prominently in all Chinese philosophy that it is central to Chinese modes of thinking in ethics, aesthetics, metaphysics and epistemology. In the Chinese life of the mind, the primary concern in ethics is how to establish the standards of inspiration for the young through exemplary teaching, in aesthetics how to acquire the real taste of beauty through rigorous discipline, in metaphysics how to understand ultimate reality from within, and in epistemology how to know in the spirit of impartiality and mutuality. Indeed, the centrality of self-cultivation compels Chinese thinkers to ground ethics in practice, aesthetics in experience, metaphysics in wisdom and epistemology in communication. The Chinese equivalent of the Greek dictum that an unexamined life is not worth living is that an uncultivated person is not yet human. A defining characteristic of learning to be human is to engage in a ceaseless process of self-cultivation. Philosophy so conceived is neither abstract theorizing nor speculative thinking but a spiritual discipline. As a spiritual discipline, the love of wisdom is a transformative act.

6 The embodiment of the Way: the Daoist approach

Self-cultivation for the Daoists requires the art of unlearning (see Daoist philosophy). While in the pursuit of knowledge one gains by day, in the quest for the *dao* one must let go, lose and be silent:

> To rarely speak - such is the way of Nature.
> Fierce winds don’t last the whole morning.
> Torrential rains don’t last the whole day.
> Who makes these things?
> If Heaven and Earth can’t make these last long-
> How much more is this true for man!
>
> (*Daodejing* 23, in Liang 1996: 223)

The constant and enduring way of nature is therefore undramatic, nonviolent, peaceful, tranquil and colourless. The precondition to emulate this is to acknowledge our fatal flaw of not knowing that we do not know:

> To know you don’t know is best.
> Not to know you don’t know is flaw.
> Therefore, the Sage’s not being flawed
> Stems from his recognizing a flaw as a flaw.
> Therefore, he is flawless.
>
> (*Daodejing* 71, in Liang 1996: 222)

Having acknowledged our ignorance, we begin to appreciate that, in the spirit of the *dao*, self-cultivation does not take the form of action:

> The softest, most pliable thing in the world runs roughshod over the firmest thing in the world.
> That which has no substance gets into that which has no spaces or cracks.
> I therefore know that there is benefit of taking no action.
> The wordless teaching, the benefit of taking no action -
> Few in the world can realize these!

(*Daodejing* 43, in Liang 1996: 222)

Even though the *dao* is ineffable, it can be experienced. The tacit 'knowledge' of non-action can help us to embody it. To experience the *dao* or to acquire a taste of it is the focus of Daoist self-cultivation:

> To know the constant is to be all-embracing;
> To be all-embracing is to be impartial;
> To be impartial is to be kingly;
> To be kingly is to be like Heaven;
> To be like Heaven is to be one with the Dao;
> If you're one with the Dao, to the end of your days you'll suffer no harm.

(*Daodejing* 16, in Liang 1996: 223)

Zhuangzi describes vividly how, for the Daoists, an experiential understanding of the *dao* is the most efficacious way of realizing the *dao* in our ordinary daily living. The relationship between the perception of what the dao is, and the spiritual journey through which the *dao* is embodied, is articulated by the language of nature symbolizing spontaneity, constant flux and incessant transformation:

> Tao [Dao] has reality and evidence but no action or physical form. It may be transmitted but cannot be received. It may be obtained but cannot be seen. It is based in itself. Before heaven and earth came into being, Tao existed by itself from all time. It gave spirits and rulers their spiritual powers. It created heaven and earth. It is above the zenith but it is not high. It is beneath the nadir but it is not low. It is prior to heaven and earth but it is not old. It is more ancient than the highest antiquity but is not regarded as long ago.

(*Zhuangzi*, in Chan 1963: 194)

The spiritual implications for this perception of the *dao* are equalizing all things and opinions, abandoning selfishness of all descriptions and attaining enlightenment by moving into the realms of 'great knowledge' and 'profound virtue'. In Zhuangzi's own style of expression, the person who has learned *dao* is able to transcend this world, all material things and all life:

> Having transcended all life, he became as clear and bright as the morning. Having been as clear and bright as the morning, he was able to see the One. Having seen the One, he was able to abolish the distinction of past and present. Having abolished the past and present, he was then able to enter the realm of neither life nor death. Then, to him, the destruction of life did not mean death and the production of life did not mean life. In dealing with things, he would not lean forward or backward to accommodate them. To him everything was in the process of destruction, everything was in the process of perfection. This is called 'tranquillity in disturbance'. Tranquillity in disturbance means that it is especially in the midst of disturbance that [tranquillity] becomes perfect.

(*Zhuangzi*, in Chan 1963: 195)

This remarkable convergence of an ontological reading of the *dao* and an existential interpretation of the true person suggests a fruitful interplay between the aloofness and elusiveness of the *dao*, and the concreteness and practicality of the Daoist experience. The *dao* as an idea is conceptually forever inaccessible, and as a way of life is experientially always present.

7 An anthropocosmic vision

It is easy to assume that the Confucians, being politically concerned, socially engaged and culturally sensitive, take self-cultivation as a this-worldly value-orientation, whereas the Daoists, being disinterested in politics, society and culture, define self-cultivation in other-worldly terms. In a deeper sense, however, Confucians and Daoists are both immersed in the same *Problematik*: how can we respond to the vicissitudes of a constantly changing world in the spirit of spontaneity without losing the inner tranquillity of the mind? In the words of a syncretic text of the Han dynasty, how can we transform together with external things but not lose our true nature? A classical formulation of this central issue is found in the *Zhongyong (Doctrine of the Mean)*:

> When emotions, such as pleasure and anger and sorrow and joy, have not been aroused, the state is called that of centrality. When these emotions are aroused and each and all attain due measure and degree, it is called the state of harmony. The state of centrality is the great root and the state of harmony is the far-reaching way of all existence in the world. Once centrality and harmony are realized, Heaven and Earth take their proper place and all things receive full nourishment.
>
> (*Zhongyong* 1)

The ‘anthropocosmic’ vision embedded in this statement is both Confucian and Daoist. Indeed, it is predicated on an ontological commitment in the ‘Appended Remarks’ of the *Yijing (Book of Changes)*: the great transformation of the cosmos is the highest standard of inspiration for human self-cultivation, and human beings can assist in the transforming and nourishing processes of Heaven and Earth and thus form a trinity with Heaven and Earth through personal self-realization. By implication, what we do in the privacy of our homes and in the practical living of our everyday existence is profoundly meaningful in a cosmological as well as in a psychological sense.

8 Discipline of the mind: the Buddhist insight

This central and enduring motif of self-cultivation philosophy has been greatly enriched by the introduction of Buddhism from India (see Buddhist philosophy, Chinese). The most obvious Buddhist contribution to Chinese self-cultivation philosophy is the discipline of the mind. An early Buddhist master, Huisi (514-77), remarked that, through concentration, we can realize the pure mind; insight derived from the realization of the pure mind enables us to perceive that all sentient beings are ‘harmoniously identified to form one body of a single character’ (Liang 1996: 225). The power of concentration helps us not only to attain calmness, stillness and purity of the mind, but also to function without the form of functioning, and to act without the form of acting. This resembles the Daoist idea of acting in the spirit of non-action.

The introduction of Buddhism was accompanied by a host of spiritual disciplines hitherto unavailable to the Daoist practitioner. Furthermore, its new perceptions of the human condition fundamentally reshaped the basic tenets of Chinese self-cultivation philosophy. The issue of ‘attachment’ loomed large in the new configuration. As Jizang (549-623) notes, ‘if there is an attachment (in the mind), there is a fetter, and one cannot obtain release from birth and old age, sickness and death, care and sorrow, pain and suffering.’ To rise above attachment and perceive things as they are, a combined effort of meditation and wisdom is required. Yet, as Huineng noted, meditation and wisdom are a unity, rather than two separate disciplines:

> Calmness [stillness] itself is the substance of wisdom; wisdom itself is the function of meditation. At the very moment when there is wisdom, then meditation exists in wisdom; at the moment when there is meditation, then wisdom exists in meditation. Good friends, this means that wisdom and meditation are alike.
>
> (Chan 1963: 433)

The use of substance and function to define the relationship between meditation and wisdom is instructive. The penetrating insight which emerges from the meditative practice is itself an illumination of the mind. Since our original nature is the source of wisdom, the meditative practice as a way of clarifying the mind enables our original nature to present itself. As long as that happens, wisdom is there. Meditation is therefore a return and discovery of the original nature whereas wisdom is the character of the purified mind. Huineng insists that the internal and sudden approach is the authentic method of true awakening (see Platform Sutra). If we do not place our trust in external practices but cultivate right views in regard to our original nature in our own minds, self-awakening is always possible. Unfortunately, our deluded minds compel us to seek wisdom by external practice and thus prevent us from awakening to our true nature.

It seems on the surface that Huineng is oblivious to the 'weakness of the will' problem. Where is the source of strength for this sudden awakening? His rival, Shenhui (670-762), offered a reasonable gradualist solution with emphasis on the power of good habits:

> After a master founder has smelted and refined the material, gold and the mineral will presently be differentiated. The more refined, the purer the gold will become, and with further smelting, the residual mineral will become dust. The gold is analogous to Buddha-nature, whereas minerals are analogous to afflictions resulting from passions. Afflictions and Buddha-nature exist simultaneously.
>
> (Liang 1996: 226)

This is the reason that, in his famous verse of self-cultivation, Shenhui perceived the body as the 'tree of perfect wisdom' (*bodhi*) and the mind as 'the stand of a bright mirror' (Chan 1963: 431). The method of self-cultivation is analogous to diligently wiping the mirror at all times so that it will never become dusty.

This common-sense approach, however, was emphatically rejected by Huineng as inadequate. Instead, he advocated sudden enlightenment as not only a more efficacious but also the only true way to understand how the mind actually works in spiritual self-cultivation. Sudden awakening is possible even for those sentient beings filled with passions and sentiments:

> It is like the great sea which gathers all flowing streams, and merges together the small and large waters into one. This is seeing into your own nature. Such a person does not abide either inside or outside; he is free to come or go. Readily he casts aside the mind that clings to things, and there is no obstruction to his passage.
>
> (Liang 1996: 226)

The freedom one experiences as the result of sudden awakening, presumably occasioned by the combined effort of meditation and wisdom, is neither cumulative nor sequential; it happens all at once. Understandably, Huineng's verse, as a response to Shenhui's formulation, is to deny the authenticity of a gradualist approach to self-cultivation:

> The mind is the tree of perfect wisdom.
> The body is the stand of a bright mirror.
> The bright mirror is original clear and pure.
> Where has it been defiled by any dust?
>
> (Chan 1963: 432)

However, in a deeper sense, the strength of Chinese Buddhist self-cultivation philosophy lies in its integrated thinking as the basis for guiding practical living in ordinary daily existence. The fruitful interaction between the gradualist and suddenist approaches enabled the Buddhist teachers, especially Chan masters, to subscribe to suddenist insight as ontological wisdom without losing sight of the gradualist effort as an existential discipline. Fazang (643-712), for example, offered the merging of the one and many as an ontological insight:

> When the feelings have been eliminated and true substance revealed, all becomes an undifferentiated mass. Great function then arises in abundance, and whenever it does, there is surely Perfect Reality. All phenomena are in great profusion, and are interfused but not mixed. The all is the one, for the relation between cause and effect is perfectly clear. As the power of the one and the function of the many embrace each other, their expansion and contraction are free and at ease.
>
> (Chan 1963: 410)

What Fazang propounded here is both an attained state of the mind and the true nature of ultimate reality such a mind perceives. With regard to self-cultivation, Fazang's ontological insight is not at all in conflict with the recommendation of Huangbo (d. 850) of the concrete steps for purifying the mind:

> First, learn to be entirely unreceptive to sensations arising from external forms, thereby purging your bodies of receptivity to externals.
> Second, learn not to make any distinctions between this and that arising from your sensations, thereby purging your bodies of useless discernments between one phenomenon and another.

> Third, take great care to avoid discriminating in terms of pleasant and unpleasant sensations, thereby purging your bodies of vain discriminations.
> Fourth, avoid pondering things in your mind, thereby purging your bodies of discriminatory cognition.
>
> (Liang 1996: 227)

Surely, the Buddhist thinkers, by their rigour of ascetic practices, persistent meditation and profound wisdom, fundamentally reshaped the spiritual landscape of self-cultivation in China, but the distinctive Buddhist traditions that emerged in the Zhongtu (the Middle Country) assumed new forms significantly different from their Indian origins. Chan Buddhism, which exemplifies the creative transformation of Buddhist teaching in China, is a paradigmatic case. The recognition that *buddha*-hood is inherent in our human nature, that our physical bodies are capable of fully realizing our nature and that we can attain *buddha*-hood in this life extends the Buddhist community to embrace the world at large and instills a sense of urgency, a heightened temporality, among the Chan practitioners. The simple and direct method Master Yixuan (d. 867) employed to inspire his disciples is a case in point:

> Time is precious. Don't make the mistake of following others in desperately studying meditation or the Path, learning words or phrases, seeking after the Buddha or patriarchs or good friends. Followers of the Path, you have only one father and one mother. What else do you want? Look into yourselves. An ancient sage said that Yanjnadatta thought that he had lost his head and sought after it, but when his seeking mind was stopped he realized he had never lost it.
>
> (Liang 1996: 228)

Huineng pointedly remarked that our self-nature, which entails the Three Bodies of Buddha (the Dharma-body, the Reward-body, and the Transformation-body), is in our physical bodies. In the classical theory of the Three Bodies, the Dharma-body is the Buddha-body in its true original self-nature that is empty (no bodily existence at all). The Reward-body is the enlightened body with real insight into the 'thusness' of things in its eternal bliss of self-enjoyment, and the Transformation-body is the compassionate manifestations of buddha-hood appearing in various forms to save people. Although the three bodies are in one, are present in all *buddhas*, and are potentially realizable by all human beings, the conditions for their realization are so complex and the time required so long that it is beyond imagination that any physical body has a chance to attain them in its own life time. Reflecting on the implications of Huineng's insistence that 'the Three Bodies are inherent in one's physical nature', Wing-tsit Chan commented:

> The doctrine of 'becoming Buddha in this very body' is a far cry from the original Indian idea that the body is a hindrance to freedom. One cannot help recalling that the Confucianists have always regarded the body as a gift from parents and as such it is a sacred trust and therefore to be well taken care of, and that for centuries the Taoist [Daoist] religion had tried in many ways, including medicine, diets, exercise, sex technique, and breath control to make the body suitable for everlasting life on earth. These are some of the roots that make Zen [Chan] essentially Chinese.
>
> (Chan 1963: 437)

9 The cultivation of the body

The Chinese heritage as a whole takes our physical nature, the body, absolutely seriously. Self-cultivation, as a form of mental and physical development and rejuvenation is an ancient Chinese art involving such exercises as rhythmic bodily movements and breathing techniques. Understandably, the classical Chinese conception of medicine focuses on healing rather than merely curing illness because its primary function is not only preventing sickness but also restoring vital energy essential for the wholeness of the body. Since the level of vital energy required for health varies according to the specific conditions of a particular person, the wholeness of body is situationally defined as a dynamic process rather than a static structure. The maintenance of health, accordingly, involves a delicate balance among a wide range of environmental, dietary, physiological and psychological factors. The rhythm of the living body is seasonal, for the body is temporal as well as spatial. The temporalization of the body as budding (spring), growing (summer), withdrawing (autumn) and preserving (winter), symbolizes longevity as both an attainment and a natural process.

Our bodies are not merely physiological entities; they are energy fields rather than conglomerates of discrete organs. Indeed, their functions are analogous to 'power stations' and 'communication centres'. The body is, therefore, a conduit through which we communicate with all modalities of vital energy in order to realize the ultimate meaning of life in ordinary human existence. Religious Daoism, especially the cult of immortality, has developed one of the richest traditions of cultivating the body as a spiritual discipline.

10 Learning to become a sage: the neo-Confucian Way

To the neo-Confucians, the central problem in self-cultivation philosophy is how to learn to become a sage (see Neo-Confucian philosophy). This is founded on the faith in the perfectibility of human nature. Zhou Dunyi (1017-73), having responded positively to the question whether or not sagehood can be learned, succinctly outlined a course of action for the spiritual journey:

> The essential is to concentrate on oneness. By concentrating on oneness is meant having no desire. Having no desire, one is vacuous while tranquil, and straightforward while in action. Being vacuous while tranquil, one becomes intelligent and hence penetrating; being straightforward while active, one becomes impartial and hence all embracing. Being intelligent, penetrating, impartial, and all-embracing, one is almost a sage.
>
> (Chan 1963: 473)

Sagehood, as the most authentic manifestation of humanity, is the result of self-cultivation. Indeed, the state of being desireless is existentially impossible for any human being to attain. This is because we observe the human condition from the perspective of the senses. If we focus our attention on the heart-and-mind rather than the senses, we can experientially understand that it is possible to rise above all desires, if only for a moment. If we can experience this even once, we recognize that sagehood, far from being an unattainable ideal, can be a standard of inspiration for daily practical living. As Zhang Zai (1020-77) notes, if we are not encumbered by the perceptions of the senses and engage ourselves in realizing fully the inner abilities of the heart-and-mind, we will appreciate sagelike qualities in our own ordinary experience.

This distinction between what we ontologically are, and what we existentially can be and must strive to become, is critical for self-cultivation philosophy. All three teachings - Confucianism, Daoism and Buddhism - hare a profound faith in human nature as a necessary and sufficient condition for self-realization (see Xing). Since ontologically sagehood, *dao* or *buddha*, is inherent in our nature, we are potentially sages, true persons and *buddha*s. Existentially, however, no matter how hard we try we can never fully realize sagehood, *dao*, or *buddha*. There is always room for improvement. Yet, although we are not what we ought to be, the ideals of what we must strive to become are inherent in our nature, indeed our bodies.

This non-dualistic thinking offers a radically different approach to the mind/body problem. The deliberate and arbitrary split of the self into *res cogitans* and *res extensa* is absent (see Mind, philosophy of). The body is never reduced to a reified corporeality, nor are the thinking and reflecting functions of the living person totally subsumed under the category of the mind. The sharp contrast between the mental and the physical totally undermines the affective dimension, feeling, as an essential feature of being human. Surely human beings are capable of willing, sensing and knowing, but feeling underlies all mental and physical activities. No expression of willpower, sense of appropriateness or cognition can be devoid of feeling. It requires a stretch of our imagination to believe that we can will, sense or know independent of how we feel. It is human to feel. Natural feelings that arise in response to the suffering of others defines who we are.

The cultivation of moral values such as humanity, rightness, propriety, wisdom, and faithfulness depends upon the nourishment of the appropriate feelings: commiseration for humanity, shame and dislike for rightness, deference for propriety and a sense of right and wrong for wisdom. Cheng Hao (1032-85) addresses this issue in his commentary on Mencius:

> Humanity implies impartiality, that is, to make (the moral principle) human. Rightness means what is proper, the standard for weighing what is of greater or smaller importance. Propriety means to distinguish (to determine ranks and functions). Wisdom is to know. And faithfulness (belief) means 'We have it'. All things have nature. These Five Constant Virtues are nature. As to commiseration and so forth (the sense of shame, the sense of deference and compliance, and the sense of right and wrong), they are all feelings. Whatever is aroused is called feeling.

(Chan 1963: 537)

This integrated vision of virtues and feelings in the context of human nature and the heart-and-mind enabled the neo-Confucians to practice self-cultivation on a daily basis. For example, Cheng Hao remarked: 'When I practice calligraphy, I am very reverential. My purpose is not that the calligraphy must be good. Rather, my practice is the way of moral training.'

Cheng Yi (1033-1107) made it clear that self-cultivation can be conceived as the site of a contest between nature and emotions, but since nature also reveals itself in feelings, it is the contest between feelings such as commiseration, shame, deference and a sense of right and wrong, and emotions such as pleasure, anger and sorrow (see Xin (heart-and-mind)):

> As the physical form appears, it comes into contact with external things and is aroused from within. As it is aroused from within, the seven emotions - called pleasure, anger, sorrow, joy, love, hate, and desire - ensue. As emotions become strong and increasingly reckless, his nature becomes damaged. For this reason the enlightened person controls his emotions so that they will be in accord with the Mean. He rectifies his mind and nourishes his nature. This is called turning emotions into original nature. The uncultivated person does not know how to control them. He lets them loose until they are depraved, fetter his nature, and destroy it. This is therefore called turning one's nature into emotions.

(Chan 1963: 548)

Following Cheng Yi's teaching, Zhu Xi (1130-1200) singled out reverence as the psychological state most congenial to self-cultivation. As a gradualist, Zhu Xi strongly advocated the necessity of a cumulative process for nurturing the right beliefs, attitude and behaviour. He urged his students to cultivate their hearts-and-minds as a daily routine:

> The mind is that with which man rules his body. It is one and not a duality, is subject and not object, and controls the external world instead of being controlled by it. Therefore, if we examine external objects with the mind their principles will be apprehended.

(Liang 1996: 230)

While he believed that when it is in a state of reverence, the mind will naturally nourish the proper dispositions for human flourishing, he insisted that the advancement of learning lies in the extension of knowledge. By implication, the investigation of things, a kind of empirical study, is relevant to and essential for moral self-cultivation.

Wang Yangming (1472-1529), however, criticized the Cheng-Zhu line of thinking for its failure to fully comprehend the true nature of moral knowledge. His perception that, in the actual practice of self-cultivation, knowing entails a transformative act serves as the basis for this doctrine of the unity of knowledge and action:

> In their learning people of today separate knowledge and action into two different things. Thereupon when a thought is aroused, although it is evil, they do not stop it because it has not been translated into action. I advocate the unity of knowledge and action precisely because I want people to understand that when a thought is aroused that it is already action. If there is anything evil when the thought is aroused, one must overcome the evil thought. One must go to the root and go to the bottom and not allow that evil to lie latent in the mind. This is the basic purpose of my doctrine.

(Chan 1963: 670)

On the surface, Wang's theory is basically therapeutic; its primary purpose is to bring about concrete results in moral behaviour. However, despite its remedial function, the inseparability of knowing and acting is predicated on the centrality of 'primordial awareness' in self-cultivation.

'Primordial awareness' (*liangzhi*), variously referred to as 'innate knowledge', 'the knowledge of the good', 'conscientious consciousness' or simply 'conscience', is what Wang takes to be the true function of human nature and the ultimate reality of all beings. This form of knowing is inherently creative; such knowledge in itself engenders new realities. Strictly speaking, 'primordial awareness' is not a reflection or meditation on external objects. Rather, it is an awareness which arises through embodying the inner patterns of things in an ever-expanding sensitivity of the heart-and-mind. Self-cultivation so conceived involves the extension of one's

‘primordial awareness’ through analogical thinking. The quality of the heart-and-mind is vitally important. Regardless how much empirical knowledge one accumulates, one’s ethical intelligence will only be enhanced when the mind is properly cultivated. Therefore, in Wang’s self-cultivation philosophy, the sincerity of the will, as an effort to purify one’s motivation, takes precedence over the investigation of things.

In the thought of Liu Zhongzhou (1578-1645), Zhu Xi’s painstaking effort to ritualize the body through reverence and Wang Yangming’s ‘direct and immediate’ approach to the self-illumination of the heart-and-mind reaches a new synthesis. Liu recommends on the one hand that we dwell in vigilant solitude in order to strengthen the roots of our intentions; on the other hand, he also recommends that this emphasis on the interiority of self-cultivation be supplemented by focused attention to the details of our daily behaviour. The authentic way of learning to be human is through examining and correcting mistakes. Self-cultivation combines the purification of an ever-deepening subjectivity with the rectification of all the mistakes made in ordinary practical living. This interplay between alertness of the subtle, incipient activation of the heart-and-mind and rigour in the ritualized discipline of the body offers a balanced programme for self-cultivation.

An elaborate project defining self-cultivation as a nine-stage effort to purify the mind was designed by the seventeenth century syncretist Lin Chao’en as an attempt to integrate the Three Teachings (Confucianism, Buddhism and Daoism) into one coherent idea of human flourishing. Lin enunciated his doctrine in a language richly textured by the symbolism of the *Yijing*. This claim that the microcosmic process in the physical body directed by the heart-and-mind actually emulates the macrocosmic process of the Heaven and Earth is characteristic of virtually all forms of self-cultivation in popular religion.

11 Modern significance

The primacy of experience, the centrality of exemplary teaching, and the necessity of personal commitment beyond reason may imply that, while such an approach is religiously meaningful, it is not philosophically significant. However, the pervasiveness of self-cultivation in all strata of Chinese society and all periods of Chinese history, clearly indicates that it is reasonable to characterize Chinese philosophy as disciplined reflections on the insights of self-cultivation. Even in Chinese Marxist literature, self-cultivation is assumed to be an integral part of the political ideology (for example, Liu Shaoqi’s essay on ‘How to be a Good Communist’) (see Marxism, Chinese). Feng Qi’s philosophy of wisdom, arguably one of the most original Chinese contributions to Marxism, focuses on the transformation of praxis into virtue-centred ethics. Self-cultivation provides the necessary background for Feng’s thought. Self-cultivation also features prominently in New Confucian Humanism. Indeed, a defining characteristic of New Confucians in the twentieth century is the prominence of the moral discourse on the learning of the heart-and-mind in their styles of philosophy.

Feng Youlan [Fung Yu-lan] (1895-1990), a major thinker under the influence of New Realism, characterized philosophy as a reflection on the human spirit, self-reflexivity and thinking about thinking. In a highly original philosophical move, he constructed his New Learning of the Principle around four cardinal concepts: principle, vital energy, substance of the *dao*, and the Great Whole. He also described Wang Yangming’s ‘primordial awareness’ (*liangzhi*) as a basic philosophical postulate. Feng’s use of propositional language in defining ‘primordial awareness’ as a postulate was severely criticized by Xiong Shili (1885-1968), one of the founders of New Confucian Humanism. Xiong insisted that ‘primordial awareness’ as an experience is a manifestation, indeed a realization of the human spirit. If it is defined merely as a postulate, the advantage of philosophical impartiality will be offset by its spiritual irrelevance. How could a mere postulate generate a profound sense of commitment to its full realization? On the surface, the difference between Feng and Xiong lies in the choice between an analytical reflection and an ethico-religious assertion. The former belongs to philosophy, whereas the latter smacks of religious or theological advocacy. At stake, however, is the role and function of self-cultivation in our definition of philosophy.

If philosophy is itself a spiritual quest and its purpose is self-knowledge, the disciplined reflection on insights ought to lead to wisdom necessary for human flourishing. ‘Primordial awareness’, the innate knowledge and innate ability that enables us to cultivate ourselves through our own effort, should not be affirmed merely as a postulate. Rather, it should be demonstrated as a presence and experienced as a reality. The danger of the propositional language is not only the misleading impression that the whole exercise is noncommittal but also the mistake in confusing the really real with an imagined possibility. We may detect a dogmatic streak in presenting

the ‘primordial awareness’ as a true presence and an experienced reality. However, the purpose is to show that philosophers must share their insights the way they experientially understand them to be. If ‘primordial awareness’ is what philosophers believe to be a genuine insight on the human condition (both Feng and Xiong, as Confucian thinkers, certainly did), then to them it must be more than a postulate.

On the surface, this may appear to be a conflict between different styles of philosophizing. Feng seems justified in having made ‘primordial awareness’ a mere postulate before he fully demonstrated its validity. After all, he could follow a series of assumptive reasons until he finally arrived at the conclusion that without ‘primordial awareness’ his whole philosophical enterprise would fall. Nevertheless, Xiong would contend that this style of philosophizing cheapens the seriousness of the spiritual exercise; it can be reduced to an inconsequential intellectual wordplay.

An underlying conviction of the New Confucian Humanists is that philosophy rooted in self-cultivation, far from being an academic discipline confined to a coterie of professionals in the ivory tower, is available to and necessary for all people. To paraphrase a statement in the *Daxue*, from the ruling minority and cultural elite to people in the street, all should regard self-cultivation as the root. If the root is not established, the Way cannot prevail; all the moral, social and political institutions instrumental for human flourishing (family, school, community, state and the world) depend upon self-cultivation for their stability, regularity, governance and peace. This personalist approach to morality, society and politics is based on the simple notion that the health of the whole is determined by the vitality of its constitutive parts. Ultimate human flourishing means that each and every member of the family, school, community, nation and the world is well-cultivated. Yet, to understand the significance of self-cultivation simply as a means to serve the ends of community well-being is one-sided. It is also an end in itself. Indeed, the justification for regulated families, functioning schools, ordered communities, governed states and a peaceful world is that they provide a wholesome environment for self-cultivation.

What is the relevance of self-cultivation philosophy to a complex modern society? A smooth functioning of the market, a vibrant democracy and the societal respect for the dignity of the person all depend upon the quality of the people involved. As we become increasingly self-interested, profit-oriented, litigious, competitive and individualistic, the need to develop a sense of public-mindedness, rightness, civility, trust and group spirit is compelling. The philosophy that enjoins us to elevate our common sense to good sense and transform the private ego into an open, dynamic and creatively transformative selfhood is vitally important for our life of the mind.

Perhaps the most enduring contribution of self-cultivation to the current style of philosophizing with emphasis on the analytical technique is to broaden the scope of rigorous thinking to include reflection on things at hand, meditation on ultimate concerns and examination of practical matters of daily living. Philosophy so conceived is no longer the privilege of a small coterie of trained professionals. Rather, it is a cultivated art accessible to all reflective, meditative and examining minds in the human community. While highly complex abstract reasoning may still characterize what teachers and researchers of philosophy do, the philosophical enterprise of self-knowledge is then an open invitation to all who cherish the value of the life of the mind. Surely, the degree of sophistication and refinement in self-cultivation varies from individual to individual and, like art, literature or music, the difference in proficiency and accomplishment between an initiating student and a virtuoso can be immense; but, to the extent that philosophy is viewed as self-cultivation, it is accessible to all members of the human community. While there is no need to delink philosophy from logic, epistemology and natural sciences, philosophy as self-cultivation or self-cultivation philosophy (they are of course distinguishable) must involve scholars in the humanities and social sciences. Indeed, for philosophy to regain the meaning and vitality as the ‘love of wisdom’ it once possessed, it must also transcend the boundaries of the ivory tower. Attention to self-cultivation is essential for such a task.

Self-deception

Philosophical work on self-deception revolves around a trio of questions. What is self-deception? Is self-deception possible? How are cases of self-deception to be explained? The extent to which self-deception is analogous to interpersonal deception is controversial, partly because certain analogies threaten to render the possibility of self-deception deeply problematic. The problems concern both the mental state of self-deceived individuals at a particular time (static problems) and the dynamics of self-deception (dynamic problems). For example, in normal interpersonal deception the deceivers know something, p, or at least believe truly that p, while getting their victims to believe the opposite, ~p. So if self-deception is strictly analogous to (normal) interpersonal deception, self-deceivers know or believe truly that p while getting themselves to believe that ~p. If this entails simultaneously believing that p and believing that ~p, self-deception may seem impossible. (For example, how can I believe that someone will read this entry while also believing that no one will read it?) Moreover, even if this state is possible, the suggestion that people can get themselves into it by deceiving themselves is problematic. It may seem, for instance, that any project describable as 'getting myself to believe what I now know to be false' is bound to be self-defeating. Self-deception may be dynamically impossible.

1 Intentional self-deception and partitioning strategies

Philosophers who deem self-deception conceptually or psychologically impossible typically contend that deceiving, by definition, is an intentional activity and that putative self-deceivers, therefore, must intentionally deceive themselves. In various time-lag scenarios, intentionally deceiving oneself clearly is possible. Paul, a pudgy prankster who has intentionally deceived others about their weight by secretly adjusting their bathroom scales, now intends to deceive himself into believing that he is lighter than he in fact is. Cognizant of his forgetfulness, the prankster adjusts his own scales for this purpose and counts on eventually forgetting that it was done. In this way, Paul may intentionally bring it about that he believes himself to be lighter than he is. In problematic cases, there is no such time lag. Rather, at some point during agents' intentional efforts to deceive themselves, they succeed in so doing. Some contend that such cases are impossible and that self-deception, therefore, is nonexistent. (These theorists suppose that self-deception is essentially intentional and involves no time lag.) Others defend the possibility of such cases. Yet others argue that intentional self-deception is remote from garden-variety self-deception and that even if the hard cases are impossible, that leaves the reality of self-deception intact.

Some philosophers propose to account for the possibility of self-deception by postulating a partitioned mind. Partitioning strategies range from postulating full-blown sub-agents with their own motives and intentions to employing modest distinctions among kinds or levels of awareness (see Modularity of mind; Cognitive architecture). In general, partitioners accept a strict interpersonal model of self-deception and seek to locate the requisite divisions within a single mind. A seriously divided mind may contain both a deceiving agent and a deceived subject. The deceiver (D) may believe that p while intentionally causing the subject (S) to believe that ~p. To the extent to which a divided mind is analogous to a pair (or group) of persons, static problems seem manageable. As you may believe that p while I believe that ~p, D may believe that p while S believes that ~p. Dynamic problems would be equally manageable. The basic idea of a representative dynamic problem has two major components. First, given that self-deceivers intentionally deceive themselves, they must intentionally follow a plan in so doing. Second, setting aside time-lag scenarios, any attempt at such plan-following would be self-defeating: just as I will not deceive you during a temporal span t, if you know what I am up to throughout t, you will not deceive yourself during t, if you know what you are up to throughout t. In a radically divided mind, S may have no idea what D is up to, and the problem vanishes.

Radical partitioners are often charged with substituting a species of 'other-deception' for self-deception. The criticism is that no human beings both deceive and are deceived by themselves on the radical view; rather, a sub-agent is the deceiver and something else is deceived. Further, the mental condition of radically partitioned persons strikes some theorists as disturbingly similar to multiple personality disorder. Surely, ordinary self-deceivers need not be so fragmented? Arguably, more modest proposals can account for self-deception.

Less radical partitioners eschew appealing to internal agents. Normally, however, their partitioning hypotheses are designed specifically to handle static problems, and dynamic counterparts remain. It has been proposed, for

example, that a person may simultaneously believe that p and believe that ~p, because the true belief may be possessed only unconsciously and therefore need not pre-empt the simultaneous holding of a contrary belief (see Unconscious Mental States). However, this does not answer the charge that intentional processes logically required for self-deception are necessarily self-defeating.

2 Departing from interpersonal models and related issues

Another approach to defending the possibility of self-deception is to motivate a departure from strict interpersonal models of the phenomenon. The assumption that deceiving is, by definition, an intentional activity drives many familiar puzzles about self-deception; and it is false. Using deceived in the passive voice, we properly say such things as ‘Unless I am deceived, I left my keys in my car’. Here ‘deceived’ means ‘mistaken’. In a corresponding use of ‘deceive’ in the active voice, to deceive is ‘to cause to believe what is false’; and not all instances of this are intentional. Your father accidentally misreads an encyclopedia article, taking it to report that p. He then tells you that p, intending to report something true but actually uttering something false. If you believe him, he has caused you to believe a falsehood: he has deceived you, in one legitimate sense of the word, but not intentionally.

This point has been exploited. When we know that people accidentally caused themselves to believe a falsehood (by innocently misreading an encyclopedia article, for example), we do not charge them with self-deception. However, when motivation enters the causal story in certain ways, a charge of self-deception seems warranted. Ordinarily, people who allegedly deceive themselves into believing that p want p to be true. For example, people who deceive themselves into believing that their spouses are not having extramarital affairs normally want it to be true that they are not so engaged, and parents who deceive themselves into believing that their children were erroneously convicted of a crime normally want it to be true that they are innocent. Owing significantly to the influence of relevant desires, Edna falsely believes that her husband, Ed, is not having an affair, in the face of strong evidence to the contrary. Is it likely that Edna first comes to believe that Ed is having an affair and then forms the intention to get herself to believe that he is not so engaged - which intention, perhaps after a bit of means/end reasoning, she successfully executes? Or is it more likely that, owing partly to her desire that Ed not be having an affair, Edna acquires or retains a false belief that he is innocent of infidelity without having come to believe that he is guilty and without intending to deceive herself?

A proper understanding of the dynamics of self-deception requires an appreciation of the ways in which motivation may bias reasoning and the formation, perseverance, and revision of beliefs. How might it happen that Edna believes that Ed is innocent of infidelity even though an impartial person, presented with the same evidence, reasonably concludes that he is guilty? Owing to her desire for Ed’s innocence, Edna may misinterpret data, reasoning, for instance, that if Ed were having an affair he would hide it and that his seemingly intimate meetings with his apparent lover in local taverns and cinemas consequently indicate that he is not sexually involved with her. Edna may even recruit Ed (in effect) in her motivated interpretive activities, by asking him for an explanation of the data, or by suggesting for his approval some acceptable hypothesis about his conduct. Further, again owing to her desire, Edna’s attention may be selectively attracted by evidence of Ed’s innocence. There is considerable empirical evidence that what we believe tends to be affected by the salience of our data; and Edna’s desire for Ed’s innocence may render corresponding data more salient than they would otherwise be. Edna may even set out to conduct an impartial investigation, but, owing to her desire, locate and focus on less accessible support for Ed’s innocence while overlooking more readily attainable support for his guilt.

All this can happen without Edna’s intending to deceive herself. Still, given the motivated way in which Edna’s pertinent belief is produced or sustained, even in the face of stronger evidence to the contrary, Edna is plausibly regarded as self-deceived. She is deceived as a consequence of her motivationally biased cognitive conduct.

The alleged requirement that self-deception be intentional is separable from another putative requirement - namely, that the person who is self-deceived in believing that p also knows or believes, at some level, that ~p. Some allege that self-deceived individuals characteristically behave in ways that clash with their sincere assertions and that this is explained by their knowing the truth at some level, which knowledge manifests itself in their overt behaviour. This is disputable. Edna, for instance, arguably is self-deceived even if she does not know or believe, at any level, that Ed is having an affair - even if her self-deception consists, in part, in a motivated failure to acquire the true belief that Ed is guilty of infidelity. Further, if Edna’s behaviour towards Ed has become cool, and if she has begun to enquire regularly of his whereabouts, this may be explained on the less demanding hypothesis that she suspects

that Ed may be having an affair. Edna may believe that Ed is faithful while also believing that there is a significant chance that she is wrong about this: ‘I believe that p, but I may be mistaken’ is utterly intelligible. In a thoroughly self-deceived person, beliefs of the latter sort presumably are absent. A self-deceived person - like a person deceived by someone else into believing that p - may be fully confident that p.

In garden-variety instances of self-deception, on this view, we do not deceive ourselves with the intention of so doing, or with the intention of causing ourselves to believe (or to cease believing) something. The absence of such an intention does not, however, preclude personal responsibility for garden-variety self-deception. Often, we are properly held responsible for unintended deceiving: for example, when we should have taken more care to get the facts straight, or to express them clearly. Sometimes, when we should have been more vigilant, we are justifiably held accountable for being deceived. This is so even when the deceiving and deceived persons are one and the same.

A thorough understanding of self-deception would clarify such related issues as the nature of belief, the influence of motivation on belief, and the structure of human minds. Certain controversial views about self-deception contravene the popular idea that belief is essentially exclusive, in the sense that a person’s believing that p is incompatible with the person’s simultaneously believing that ~p. Various discussions of the dynamics of self-deception illuminate the influence of motivation on belief. The literature also features a lively debate about the extent to which the human mind is unified and about the range of entities (sub-agents, for example) to which such mental items as beliefs, desires and intentions are plausibly attributed.

Self-deception, ethics of

Self-deception is complicated and perplexing because it concerns all major aspects of human nature, including consciousness, rationality, motivation, freedom, happiness, and value commitments. In a wide sense, 'self-deception' refers to intentional activities and motivated processes of avoiding unpleasant truths or topics and the resulting mental states of ignorance, false belief, unwarranted attitudes, and inappropriate emotions. Deceiving oneself, like deceiving other people, raises a host of questions about immorality. These include whether self-deception is always immoral or only when it conceals and supports wrongdoing; whether self-deception about wrongdoing and character faults compounds or mitigates guilt for causing harm; how important the value of authenticity is, and whether it can be sacrificed in an attempt to cope with reality; what the relation is between self-deception and responsibility; and whether groups can be self-deceived. Ultimately, the moral status of any instance of self-deception depends on the particular facts of the case.

1 Explaining wrongdoing

The activities and the mental states involved in self-deception - especially the suggestion that we can wilfully get ourselves to believe the opposite of what we know is true - seem paradoxical in ways that have generated a large literature in epistemology and philosophy of mind (see Self-deception). That literature is germane to the moral issues, especially as it serves to clarify the extent of voluntariness in deceiving ourselves.

Self-deception is objectionable when it camouflages and supports greed, cruelty and other forms of wrongdoing. Moreover, often the first step towards self-reform is to remove self-deception about our character faults. And we would make fairer appraisals of other people if we were less self-deceiving about condemning them and excusing ourselves. Or so traditional ethicists have contended.

In his discussion of this in two early lectures (1722), Joseph Butler focused on two contexts. First, when moral rules are vague we tend to interpret them in ways convenient to ourselves. For example, we employ legalistic ruses in narrowly interpreting duties to help others and prohibitions against corruption. Second, we excuse our overt violations of clear duties so as to make them 'sit a little easy' in conscience. In both contexts, our motives might be general selfishness or specific passions. Our tactics include rationalization, wilful ignorance, and systematic ignoring. Having (and using) suspicions and partial knowledge of our faults, we avoid further inquiry, closing 'the eyes of the mind' as easily as those of the body. Because the avoidance is intentional, Butler concludes that self-deception compounds rather than lessens guilt for harming others and for corrupting our own consciences. It makes us hypocrites before others and also 'inner hypocrites' who culpably pretend to ourselves that we are better persons than we are.

Kant (1797) went further in suggesting that self-deception about virtually any topic - not just immorality - can indirectly cause violations of duties to others, either by making us ignorant of morally-relevant information or by encouraging habits of self-deception. Kant's view is implausible regarding many examples but it has some plausibility regarding general habits of engaging in self-deceit.

David Pears (1984) and Alfred R. Mele (1987), among others, have explored parallels and interactions between self-deception and moral weakness (see Akrasia). Self-deception explains many instances of acting against our better judgment by revealing how we blur that judgment or ignore morally relevant information. Even when moral weakness is fully conscious, self-deception causes a loss of moral perspective that might have prevented it. Conversely, some self-deception may itself qualify as moral weakness in so far as we voluntarily violate our standards of morality and rationality.

2 Authentic values

No philosopher was harsher in condemning self-deception ('bad faith') than Jean-Paul Sartre (§3). His condemnations were made despite and partly because of his renunciation of traditional beliefs in objectively justifiable values (see Existentialist ethics §3).

Sartre (1943) defined authenticity as fully acknowledging our complete freedom to choose values and to interpret the world in light of them (see Existentialist ethics §§1-2). By definition, authenticity is incompatible with

self-deceptive excuses and evasions. The worst self-deception is the direct denial of freedom of consciousness because it leads to violating other persons' freedom of conduct, for example through anti-Semitism or political oppression. Yet self-deception about all topics, not just about freedom in general, implies a cowardly refusal to acknowledge our freely chosen mental states and actions. Tactics of self-deception include quick oscillations of attention towards pleasing aspects of our lives and away from anxiety-producing ones. For example, we affirm our freedom ('transcendence') in so far as it promises happiness, but we appeal to hard facts ('facticity') whenever it assuages the anxieties in admitting responsibility for 'authoring' our choices. The fundamental strategy ('original project') in self-deception is to distort the standards of rationality for belief by exaggerating favourable evidence for what we want to believe, disregarding contrary evidence, and resting content with minimal evidence for pleasing beliefs. Sartre's discussion is often insightful, but he conflates key distinctions such as those between free consciousness and free conduct and between causal responsibility and moral accountability.

Nietzsche (1888) offered a more nuanced critique of self-deception than Sartre (see Nietzsche, F. §9). Certainly he could be equally harsh in condemning traditional beliefs in the objectivity of moral values, with the possible exceptions of honesty and courage. Perhaps inconsistently, however, he praised the need for some self-deception in asserting our 'will to power' in developing and living according to authentic value-perspectives.

A more traditional approach to authentic values and personal identity retains the traditional faith in objective moral values by reference to which authenticity is understood. This approach does not entail dogmatism and leaves room for a pluralistic conception of diverse forms of goodness from which we choose in creating meaningful lives (see Moral pluralism). On this view, the authentic self is honestly responsive to general moral requirements, attuned to the particular goods we care most deeply about, and courageous in dealing with ineluctable realities such as death.

3 Healthy coping

Despite claims of neutrality, psychologists and social scientists who discuss self-deception frequently presuppose evaluative perspectives. Those who focus on mental illness emphasize the harmful aspects of self-deceiving 'defence mechanisms'; those who focus on healthy behaviour stress the value of self-deception as an adjustment mechanism.

Although Sigmund Freud (1920) rarely used the term 'self-deception', many of his followers interpret defence mechanisms (such as repression, projection, and sublimation) as strategies of self-deception. Using these strategies, the ego (the coping part of the mind) defends itself against onslaughts from the id (unconscious sexual and aggressive desires), the superego (socially instilled values), and external reality. In his early work Freud portrayed the ego as entirely conscious, but later he emphasized that an unconscious part of the ego engages in defence.

Cognitive psychologists have explored the positive roles of self-deception in promoting mental wellbeing, especially in maintaining healthy self-esteem by exaggerating our virtues, supporting optimism by playing down risks and creating illusions of control, and coping with traumatic events and threatening uncertainties. Similarly, sociobiologists hypothesize that we evolved as creatures who compete more successfully when we can deceive ourselves into believing the falsehoods we perpetrate on others (in order not to betray the deception with behavioural signals). These scientists provide needed correctives to one-sided condemnations of self-deception by Kant and Sartre.

4 Ambiguous responsibility

Responsibility for self-deception is obscure and ambiguous because the notion suggests a self divided against itself, rather than a unified agent, accountable for its voluntary choices.

In *Self-Deception* (1969), Herbert Fingarette linked self-deception to wider issues about personal identity and divided selves. In his view, self-deceivers pursue 'engagements' (ways of participating in the world) that they disavow. Disavowal implies a refusal to become explicitly conscious of engagements and also of the activities involved in concealing them. More fundamentally, disavowal constitutes a refusal to integrate disavowed engagements into the network of other engagements that comprise the dominant aspects of one's personality. Isolated and without rational supervision, disavowed engagements can wreak havoc on oneself and others. We are responsible for initiating disavowal, but responsibility becomes ambiguous in so far as we lose control over

disavowed engagements.

Fingarette has been criticized for being too sympathetic to psychoanalysis and insufficiently rooted in more empirical psychology (although it should be noted that his book inspired many subsequent empirical studies of self-deception). It has also been noted that he unhelpfully plays down cognitive terms like ‘belief’ and ‘knowledge’ as he shifts to action-oriented terms like ‘avow’ and ‘disavow’. Finally, he has been accused of overgeneralizing about the moral ambiguities of (all) self-deception, rather than attending to the moral variety of particular cases.

5 Collective self-deception

Collective self-deception is self-deception by entire groups who share false beliefs and unwarranted attitudes. Charges of collective self-deception are both provocative and contentious. Thus, Marxists portray workers who accept capitalism as suffering from ‘false consciousness’, that is, illusions about the economic origins and political implications of economic ‘ideologies’ (see Marx, K. §10; Ideology §1). Some feminists portray satisfied homemakers as having ‘internalized’ patriarchal ideologies. Religious and nonreligious thinkers criticize each other’s perspectives as self-deceiving. And in *1984* (1949), George Orwell suggested that political oppression is sustained by fostering widespread ‘doublethink’, a process he described in terms reminiscent of Sartre’s description of bad faith.

Some charges of collective self-deception are illuminating, although troublesome in thinking about personal and collective responsibility (see Responsibility). In so far as my self-deception is pressured or encouraged by strong social forces, am I less blameworthy because my autonomy is lessened, or is my responsibility compounded because I allowed myself to be a passive conspirator? (In *Invisible Man* (1947), Ralph Ellison suggests that both may be true, in different respects.) Nevertheless, allegations of collective self-deception are easily abused and tend to degrade the concept of self-deception into a rhetorical weapon that undermines tolerance. Ascriptions of self-deception about morality are rooted most firmly where values are clear and well-justified; they are best avoided in contexts where morally reasonable persons interpret and balance values in alternative ways.

6 Conclusion

Self-deception is morally complex for two main reasons. First, in evaluating particular instances and in ascribing responsibility for their consequences, attention must be paid to an array of contextual factors: what the self-deception is about, what motivates it, which obligations it threatens, the degree of harm it causes to oneself and to others, the vital needs it may serve, how much control an individual has in initiating and sustaining it, what help is available to overcome it, and whether it is episodic or habitual. When motives are good and consequences are desirable, self-deception may be excusable, forgivable, desirable, or simply comic, depending on the circumstances. When motives and consequences are evil, as they were in the self-deception that Albert Speer ascribes to himself in his memoirs, *Erinnerungen (Inside the Third Reich)* (1969), self-deception becomes a form of cruelty and callous moral negligence.

Second, different moral emphases can be brought to bear in understanding self-deception. We may agree that honesty (with oneself and others) is an important virtue, but exactly how important relative to other virtues is open to dispute and reasonable disagreement (see Truthfulness). The insistence that honesty is always paramount and forbids all self-deception can result in inhumane neglect of other important values such as love and self-respect. Indeed, idealistic demands for perfect honesty can themselves be permeated with self-deceptive self-righteousness, as playwrights remind us: see Molière’s *Le Misanthrope (The Misanthrope)* (1666), Henrik Ibsen’s *Vildanden (The Wild Duck)* (1884), and Eugene O’Neill’s *The Iceman Cometh* (1957). It is equally clear, however, that love and self-respect are themselves undermined when habitual self-deception distorts caring for others and for oneself.

Self-realization

'Self-realization' is the development and expression of characteristic attributes and potentials in a fashion which comprehensively discloses their subject's real nature. Usually, the 'self' in question is the individual person, but the concept has also been applied to corporate bodies held to possess a unitary identity.

What constitutes the self's 'real nature' is the key variable generating the many conceptions of self-realization. These can be grouped broadly into two types: (1) the 'collectivist', in which the self-realizing lifestyle, being either the same for all or specific to a person or subgroup of people, is ultimately definable only in the context, and perhaps with reference to the common purposes, of a collective social body; (2) the 'individualist', in which a person's self-realization has no necessary connection with the ends of a particular community.

As an ethic, self-realization can be proposed as the means to achieve a life identified as good by some criterion independent of the self-realizing process, or held to be that which actually defines the good. Its critics typically argue that human nature is such that any equation of 'self-realization' and 'goodness' is implausible or undesirable.

1 Collectivist self-realization

Aristotle's moral and political work, especially *Nicomachean Ethics*, is an enormously influential example of a self-realizationist theory, which holds that the development and expression of people's potentials is the goal for the best moral - and, for Aristotle, political - life (see Aristotle §§20-6). Using 'self-realization' as much to describe the good society as the good person, he proceeds from the belief that humans naturally possess a unique, essential state of being - the life of reason-guided activity - to argue that achievement of this state is the goal (*telos*) towards which normal human development aims (see Human nature §1). Subsequently, he identifies those personal dispositions and social institutions necessary for securing this end.

Aristotelian self-realization is collectivist not only in the sense of its essence being a shared characteristic but also in its requirement that it be achieved within a very particular form of social life: the polis or city-state. Theoretically, it permits some diversity across the range of self-realizing lives. Other versions of collectivist self-realization can be much stricter in detailing exactly what form of life is required, tying the 'real nature' of the self to specific social roles or the performance of onerous moral duties. Often, these doctrines adopt a version of positive liberty by characterizing self-realization as 'true freedom', which facilitates their descriptions of non-self-realizing lifestyles as not 'really' wanted by people despite any 'mistaken' preferences to the contrary (see Freedom and liberty).

The sustainability of collectivist conceptions in Western thought was weakened significantly (particularly from the seventeenth century onwards) with the emergence of more atomized, individualistic notions of the self, generated not least by a growing appreciation of human diversity. This distinctively modern form of identity self-consciously sought individuation, conceptualizing the self and its ends apart from any particular, metaphysically independent moral order. Increasingly, people were seen as empowered to direct their own lives according to their own desires. The postulation of substantive shared natures and comprehensive collective purposes, and the equation of their realization with human freedom and morality, became much less credible. Indeed, for some, such conceptions were downright pernicious in their attempt to attribute an artificial uniformity to human nature.

That some versions of collectivist self-realization remained vibrant in the nineteenth and twentieth centuries was due largely to Hegel and his intellectual heirs, but the transformation in the concept of the individual left its mark on them (see Hegelianism). Reflecting high Enlightenment optimism over the goodness of human potential and the continuing reconcilability of freedom, morality and social order, their theories held that self-realization involved the expression of full individuality and a unification of every self with each other in a qualitatively new, yet genuinely communal, form of social life (see Enlightenment, Continental). Marxism became the most influential exponent of this approach, viewing self-realization as based upon the capacity for free creative labour supposedly shared by all and insisting that, under full communism, the free self-realization of each would ultimately be dependent upon the free self-realization of all (see Marx. K.).

2 Individualist self-realization

Romanticism was the prime influence in bequeathing conceptions of self-realization to the individualized notions of selfhood, prompting a view of the self as invested with a capacity to develop - freely and creatively - a naturally given potential to lead a morally worthy, aesthetically stimulating life (see Romanticism, German). This was distinguishable from the collectivist variant in that the self-realizing lifestyle was held to be unique to each individual and no longer required reference to the purposes of a larger whole for its full meaning. Many individualistic conceptions nevertheless stressed self-realization's dependence upon specific forms of community as necessary means for its achievement, retaining the concept's potential as critic of degenerate societies and inspiration for social and political reform. The emphasis had nevertheless switched to the individual's uniqueness as the end in itself and in some other versions, notably that of the later Rousseau, modern society is seen as so irredeemably corrupt as to require virtual abandonment by the self seeking realization (see Rousseau, J.-J.).

The 'individualistic' label should not obscure the fact that these conceptions generally reaffirm the idea that there are certain features common to everyone's self-realization: similar kinds of potential, for example. This preserves the viability of 'self-realization' as something identifiably separate from other ways of living. Yet the same sensitivity to human diversity which undermined the collectivists' credibility poses serious challenges here, too. One may doubt that even the relatively minimal shared features specified by these conceptions really exhaust all cases of what self-realization might legitimately involve. One may believe there is no warrant for characterizing self-realization as anything other than however individuals would like to live, in which case the need for - perhaps even the very intelligibility of - the concept as distinct from, say, mere 'autonomy' must be questioned (see Autonomy, ethical).

Alternatively, if self-realization is still defined in sufficiently substantive terms to avoid a content-draining equation of it with 'whatever one chooses to be or do', but one also desires to respect individuals' autonomy (as individualistic conceptions usually profess to do), self-realization very readily reduces simply to one lifestyle option among many which might be chosen by free people. Though this need not force a denial that it is the best form of life, preference for self-realization over respect for autonomy as a social and political ethic consequently seems to lose justification.

3 Further problems

The concept's detractors may also be critical of its presentation as an ethical standard, in which self-realization is defined by some independent specification of goodness or is deemed to be what actually yields the criterion of goodness itself (see Perfectionism). Arguing that humanity's behaviour reveals nothing good in people's potentials, they may contend that self-realization is far from the best route to goodness and patently unsatisfactory as a defining characteristic of the good. Alternatively they may urge that, even if it is not intrinsically bad, self-realization creates a 'culture of narcissism', encouraging those forms of selfhood which, while perhaps harmless enough in themselves, nevertheless fail to show respect for others and threaten to enervate social life itself.

Critics also claim that the self-realization of people with morally positive natures might still entail struggle, frustration and disillusionment, which could be worse (in hedonistic or any other terms) than the outcome of a non-self-realizing life. Equating 'good' directly with 'self-realization' theoretically dissolves such worries ('whatever pain it may cause, self-realization remains the best by definition'). Yet this move seems eminently resistible if we consider the gamut of human potentials to be profoundly ambivalent in character. There are both good and bad potentials, with some people possessed of a surfeit of one and most, perhaps, laden with a mixture of both. To yield this plausible discrimination, we clearly need to conceptualize 'good' independently of 'self-realization'. However, the same ambivalence militates against the thought that self-realization is the best way to achieve an independently defined good: the latter might require the restraint of at least part of one's nature.

Furthermore, the very concept of the self as possessed of a given identity capable of realization has been challenged in postmodernist thinking (see Subject, postmodern critique of the). While many conceptions of self-realization readily accept that the 'givenness' of the self's nature does not preclude its fluidity and revisability, postmodernism wants to resist any such fixity and, accordingly, prefers putatively distinct notions of self-*creation*.

Yet 'self-realization' can be revised to insist that the highest realizable values must spring from part of human nature, urging that we learn to identify with that part which promises the most fulfilling and sustainable form of

personal and social life, and fashion our lifestyles accordingly. Green moral and political thought has utilized the concept thus, interestingly de-emphasizing its usual ‘activist’ insistence upon personal striving in a reconciliation of the self with nature which is more reminiscent of the spiritual, contemplative self-realizationist ethics in Eastern philosophy (see Environmental ethics §2; Buddhist philosophy, Indian §1).

If it can, then, be rendered a distinctive and attractive concept, ‘self-realization’ might plausibly continue to be a central concept in critiques of those ways of life and forms of society which leave people unfulfilled and alienated.

Self-respect

Persons are said to respect themselves when they have an appropriate sense of their own worth either as persons generally or as individuals occupying particular roles. In respecting themselves as persons, people may recognize their worth as persons ('recognition' self-respect) or value the positive aspects of their character ('evaluative' or 'appraisal' self-respect). On the 'subjective' view of self-respect, persons have self-respect so long as they value themselves according to their own standards of worthiness. On the 'objective' view, there are certain attitudes or actions that show self-respect, regardless of whether the agents exhibiting them are conforming to their own standards. Self-respect plays a central role in the ethical philosophy of Kant and the political philosophy of Rawls. Kant maintains that persons have a duty to respect themselves, which consists in regarding themselves as equal in moral status to other persons. Rawls holds that a just society must provide the social bases of self-respect for all citizens, for without self-respect, their lives are severely diminished. In this same spirit, some critiques of oppression emphasize the injustice of robbing people of their self-respect, which is often a consequence, it is claimed, of being oppressed.

1 The concept of self-respect

Self-respect is a multifaceted notion involving a constellation of attitudes, beliefs, desires, dispositions, commitments, expectations, actions and emotions that express or constitute one's sense of one's worth. It includes a recognition and understanding of one's worth, as well as a desire and disposition to protect and preserve it. One can respect oneself as a person, as when one stands up for one's rights, or in a specific role or capacity, as when one adopts the code of ethics associated with one's work or profession. One may also merit one's own respect, as a person or as the occupier of a role, by conducting oneself honourably or by living up to one's standards. Since philosophers tend to be concerned with respect for oneself as a person, 'self-respect' will henceforth be assumed to have persons as such as its object.

Most writers on self-respect agree that it can be divided into two kinds, according to its appropriate grounds. Robin Dillon (1992a) calls these two kinds 'recognition' self-respect and 'evaluative' self-respect. The latter kind is also widely referred to as 'appraisal' self-respect (see Respect for persons §1). Recognition self-respect is a type of regard towards oneself that all persons are obliged or entitled to acquire. Unworthy attitudes or conduct, such as servility or needless self-deprecation, are viewed as evidence of, or as constitutive of, its absence. The label 'recognition self-respect' derives from the fact that the attitude to which it refers consists primarily in recognizing that one is a person and weighing appropriately this fact in deliberation and action. Such recognition is not to be understood as mere acknowledgement of the fact that one is a person. It also includes appreciating the special status one has as a person and that this status may require certain kinds of responses, conduct, or restraint. One is obliged or entitled to respect oneself in virtue of the fact that one is a person.

The concept of recognition self-respect relies heavily on a normative conception of the person. Moreover, one must have some sense of what that conception entails to understand what would count as respecting or showing disrespect to persons. It follows that we can infer much about philosophers' understanding of the nature and status of persons from their accounts of the content of recognition self-respect. The notion of the person that is presupposed by most contemporary discussions of recognition self-respect is either strictly Kantian, or Kantian in spirit (see Respect for persons §2). On this view, persons are essentially autonomous rational agents who possess a special worth grounded in their capacity for moral agency and who enjoy a status of moral equality with other persons on the basis of this special worth (see Autonomy, ethical). Recognition respect for oneself as a rational autonomous agent involves acknowledging and appreciating one's autonomy, one's rationality, the value one has in virtue of having these capacities, and the moral status of equality that is grounded in this shared value (see Kantian ethics).

In contrast with recognition self-respect, which all persons are required or entitled to secure, evaluative self-respect is a kind of self-respect that individuals may or may not merit and may merit in varying degrees. Where the presence of recognition self-respect prompts us to engage in worthy conduct or refrain from engaging in unworthy conduct, the presence of evaluative self-respect results from an assessment of conduct already undertaken. Because persons must earn evaluative self-respect by conforming their actions, emotional responses,

attitudes and so on to certain standards of worthiness, not everyone is entitled to evaluative self-respect, and some people's evaluative self-respect is unwarranted. Likewise, some people's lack of evaluative self-respect is also unwarranted. The normative ground of evaluative respect is the quality of one's moral character and those actions that reflect it. One merits evaluative self-respect, in other words, not in virtue of *being* a person, but because of the virtue *of* one's person.

Self-respect is distinct from self-esteem, though the latter notion bears some resemblance to evaluative self-respect. Both evaluative self-respect and self-esteem involve having a favourable opinion of oneself that arises from an assessment of one's traits or actions. Moreover, both attitudes can be undeserved as well as deserved but absent. None the less these two notions differ in their respective normative grounds. A favourable regard for oneself based upon features that do not bear directly upon one's moral character, such as one's sense of humour or one's having won a chess match, is self-esteem. Evaluative self-respect involves the positive regard one has for oneself based upon one's moral character. Although this method of distinguishing self-respect from self-esteem is by no means uncontroversial, it has the advantage of allowing us to distinguish clearly the positive attitudes towards oneself that are directly relevant to morality and those that are less so. Evaluative self-respect, since it involves one's moral character, is certainly an appropriate subject for moral theorizing. Self-esteem, in contrast, if it is relevant to morality, is so indirectly.

On the preceding account, recognition self-respect was described as an objective notion. That is, it was assumed that there are certain attitudes, dispositions and responses that a person *must* have in order to be adequately self-respecting. Those who propound an objective view would probably claim, for instance, that persons who habitually ingratiate themselves with others for personal gain are lacking in recognition self-respect. According to the subjective view, on the other hand, so long as such persons do not *themselves* regard ingratiation for personal gain as objectionable or 'beneath them', their self-respect is intact. It is compromised only if they behave in ways that *they* judge to be inappropriate. When moral philosophers claim that all persons ought to have recognition respect for themselves, they are generally treating self-respect as an objective concept. Their claim expresses the idea that all persons, regardless of those persons' own views of what is fitting, ought to value their rights, assert their needs when appropriate, formulate and commit themselves to ideals and goals worthy of them as persons, abstain from self-destructive behaviour, avoid subordinating themselves to others unnecessarily and take responsibility for their conduct.

Evaluative self-respect can also be viewed either as an objective or as a subjective notion. Regarded as an objective concept, evaluative self-respect is judged to be warranted only if the standards by which one has appraised oneself positively are morally worthy. As a subjective concept, evaluative self-respect is seen to be warranted so long as one's positive self-assessment is based upon standards that one deems worthy of oneself.

2 Self-respect in moral and political philosophy

Though many philosophers have remarked upon self-respect, or related notions such as pride, integrity and dignity, self-respect figures most prominently in the work of Kant and Rawls. In *Die Metaphysik der Sitten (Metaphysics of Morals)* (1797), Kant claims that persons have a duty to respect themselves. Self-respect, on his view, is a valuing stance that one wilfully adopts or neglects to adopt towards oneself. It consists in an understanding and appreciation of the equal moral status one shares with other persons and a disposition to act in ways that express this understanding and appreciation. The requirement that persons regard and treat themselves as the moral equals of others is grounded in Kant's contention that all rational beings have a special moral value, which he calls 'dignity', that is itself rooted in our capacity for autonomous rational agency. Since every person as such has dignity, each person as such is equal in basic moral status to every other person and ought to appreciate this fact and act accordingly.

Our special moral worth, Kant claims in *Grundlegung zur Metaphysik der Sitten (Groundwork of the Metaphysics of Morals)* (1785), requires that all persons be treated and treat themselves as ends in themselves and never merely as a means to another's ends. In other words, the capacity of rational agents to set ends freely for themselves should be treasured and respected by all (see Kant, I. §§9-11). This duty, which is one formulation of the categorical imperative, has been interpreted by some philosophers as a duty to respect others and to respect oneself. For Kant, the requirement that we respect ourselves consists not only in a duty to regard ourselves as having the same moral standing as others, but also in an array of duties requiring us to value our autonomy and

rational agency and to treat ourselves in accordance with our special moral status.

In contrast to Kant, John Rawls views self-respect as an entitlement rather than a duty. In *A Theory of Justice* (1971), he maintains that justice requires that self-respect, or more precisely its social bases, be provided for all members of a society. Moreover, he sees self-respect not as an attitude that individuals may wilfully adopt, but as a social good that can be secured by individuals only when certain social and political conditions prevail. He defines self-respect as a conviction that one's plan of life is worth pursuing accompanied by the belief that one is well-suited to pursue it. The value of self-respect, Rawls claims, lies in the fact that no one can carry out or achieve their aims adequately without it.

For Rawls, civil equality is the key to citizens' acquiring and maintaining adequate self-respect. In the absence of civil equality, those with fewer rights and privileges will regard their life plans as less worthwhile than the life plans of citizens with more rights and privileges, for, by depriving certain citizens of goods essential to the effective pursuit of their ends, a society implies that the ends of those so deprived have a lesser value. Since self-respect is fundamental to the basic wellbeing of all persons, it follows that principles prescribing the design of basic social structures are just only if they foster or do not hinder civil equality. The two principles of justice proposed by Rawls, the equal liberty principle and the 'difference principle', are designed to ensure civil equality and hence help guarantee self-respect for all citizens.

Influenced by Rawls' realization that self-respect is largely a product of one's social and political circumstances, some political theorists have employed the notion of self-respect in their critiques of the oppression of white women, people of colour, and gays and lesbians. These writers point to the damage done to the self-respect of members of groups that are marginalized, stigmatized or exploited by the dominant culture. Oppressed people may internalize the disparaging images and views of them produced by the dominant culture and hence come to see themselves as inferior or as undeserving of equal treatment. Some writers discuss the ways in which both individual and collective resistance to oppressive institutions, actions and images can empower those who suffer from oppression, thereby augmenting and reinforcing their sense of worth. Boxill (1976), for example, claims that oppressed people can have faith in their worth only if they protest against injustices done to them. In the course of discussing the relation between oppression and self-respect, some theorists have attempted to reconceive traditional conceptions of self-respect so as to expunge from them features that are judged to reflect or champion objectionable aspects of the dominant culture. Dillon (1992b), for example, has argued that the Kantian notion of the person as an independent, autonomous, self-legislating will that underlies most conceptions of self-respect is androcentric (see Feminist ethics §4).

Recent philosophical explorations of self-respect have thrown into relief its value and significance. They have shown that self-respect is a central component of human wellbeing, since its absence is painful and debilitating, and illustrated its connection with many other important moral and social values such as rights, autonomy, dignity, freedom and equality.

Sellars, Wilfrid Stalker (1912-89)

Wilfrid Sellars was among the most systematic and innovative of post-war American philosophers. His critical destruction of the 'Myth of the Given' *established him as a leading voice in the Anglo-American critique of 'the Cartesian concept of mind' and in the corresponding shift of attention from the categories of thought to public language. His own positive views were naturalistic, combining a robust scientific realism with a thoroughgoing nominalism which rejected both traditional abstract entities and ontologically primitive meanings. In their place, Sellars elucidated linguistic meaning and the content of thought in terms of a sophisticated theory of conceptual roles, instantiated in the linguistic conduct of speakers and transmitted by modes of cultural inheritance. He combined this theory with a form of 'verbal behaviourism' to produce the first version of functionalism in the contemporary philosophy of mind. Besides his profoundly original philosophical contributions, his long career as a distinguished teacher and influential editor earned him justified acclaim as one of the definitive figures of the post-war period.*

1 Life and works

As the son of the eminent Critical Realist philosopher Roy Wood Sellars, Wilfrid Sellars' own philosophical calling was almost preordained. Educated at the University of Michigan and as a Rhodes Scholar at Oxford, he held positions at the University of Iowa, the University of Minnesota and Yale University before becoming University Professor of Philosophy and Research Professor of the Philosophy of Science at the University of Pittsburgh, where he remained from 1963 until his death. In 1950, with Herbert Feigl, he founded the first scholarly journal explicitly devoted to analytic philosophy, *Philosophical Studies*, edited jointly until 1971 and by Sellars alone for three more years.

Sellars saw post-war philosophers as confronted with two 'images', each of which laid claim to being a (potentially) complete picture of man-in-the-world - the 'manifest image', which had been the focal concern of 'perennial philosophy' from Plato and Aristotle to Strawson and Austin, and the 'scientific image', a complex understanding of man-in-the-world still in the process of emerging from the fruits of theoretical reasoning. Philosophy was challenged to explore the possibility of a 'stereoscopic understanding', in which the two images would become 'fused' into a single synoptic vision. Sellars' writings are consequently dialectical and synthesizing, typically undercutting or evading accepted dichotomies and attempting to mediate conflicting intuitions. They are shaped by the standing conviction that it is a philosopher's duty not merely to show that a received position has gone wrong, but also to explain why and how it could ever have appeared to be right.

2 Ontological perspectives

Along with Wittgenstein, Sellars figured among the pre-eminent contributors to the twentieth century's thoroughgoing critique of Descartes' picture of first-person privileged access to the states of a thinking substance (see Descartes, R.; Privacy). Unlike Wittgenstein, however, Sellars proceeded to develop a positive reconception of the problem space traditionally centred on a dualism of bodies and minds as a transposition of a more fundamental dualism of facts and norms (see Dualism; Fact/value distinction). Kant's analysis of the distinct contributions of the sensibility and understanding in perceptual experience became the guiding thread for Sellars' further sharp separation of problems regarding 'raw feels' from questions regarding intentional (object-directed) thought.

Along with Quine, but without his global rejection of semantic, mental and modal contexts, Sellars helped consummate the shift of semantic attention from the categories of thought to those of public language. Sellars differs from Quine, too, in that his own rejection of Cartesian models of the mind never issued in a correlative (radically behaviourist) abandonment of inner episodes *per se*. Instead, Sellars' critique of the positivist picture of scientific theories enabled him to develop an alternative, thoroughly realistic, understanding of sophisticated scientific inquiry in terms of which the status of concepts pertaining to inner episodes could be constructively understood on the model of theoretical discourse (see Scientific realism and antirealism; Theories, scientific).

Sellars' fundamental metaphysical conviction that the distinguishing mark of the real is the power to act or be acted upon was reflected in his thoroughgoing naturalism. This, in turn, imposed strong nominalistic constraints,

not only on the overall synoptic project, which consequently needed to find a place for mind that did not require independent ontological status for intentional entities, but also on traditional categorial ontology, which could legitimately maintain the reality of abstract entities only if it were possible simultaneously to supply an adequate account of their place within the causal order, broadly conceived. Sellars' response to both of these naturalistic challenges was to develop a sophisticated theory of conceptual roles at the heart of which was the idea that one and the same item could be at once both a causally evoked response to the environment and a normatively significant item in a rule-governed network of reasons. On Sellars' view, a person's grasp of a concept, for example, the concept 'red', consists precisely in their differential disposition to produce such inferentially articulated responses to red things (see Semantics, conceptual role).

Sellars consequently proposed to interpret both categorial ontological idioms and mentalistic intentional contexts in terms of a semantic discourse fundamentally conceived in terms of the inferential roles of public 'natural linguistic objects'. Like Rudolf Carnap, Sellars embraced a form of 'linguistic nominalism', which treated traditional categorial discourse as the classificatory discourse of a functional metalanguage transposed into the 'material mode of speech'. Unlike Carnap, however, he refused to identify the extensional constructs of 'pure' formal syntax or semantics with their corresponding 'descriptive' pre-philosophical counterparts, arguing that to do so is to fail to acknowledge properly the irreducibly normative aspects of syntactical and semantical words functioning as such.

In the philosophy of mind, Sellars adopted 'psychological nominalism', the denial that any sort of commerce with abstract entities is an essential ingredient of mental acts, and espoused instead what he came to call 'verbal behaviourism', according to which the primary sense of (occurrently) thinking that-*p* is a 'thinking-out-loud that-*p*', that is, in first approximation, an event of candidly and spontaneously saying *p* (see Behaviourism, methodological and scientific; Language of thought). The conceptual framework of inner episodes was to be understood as built upon the semantical characterization of overt verbal episodes in a manner analogous to the way in which, for instance, the framework of molecules is built on the observable behaviour of gases. On Sellars' account, the concept of a thought is fundamentally the concept of a causally mediating logico-semantic (inferential) role player, the determinate intrinsic ontological (empirical) character of which is left open. The identification of such intentionally-characterized inner episodes with, for instance, occurrences in an organism's central nervous system thus generates no ontological tension, and the manifest image's conception of persons as thinkers can fuse smoothly with the scientific image's story of complex material organisms. These proposals constituted the original version of functionalism in the contemporary philosophy of mind, the subsequent manifold varieties of which were both facilitated and directly or indirectly inspired by the theoretical space of philosophical options they had opened (see Functionalism).

As in the case of thoughts, Sellars argued that talk about sensations ('raw feels') can also usefully be interpreted on the model of a species of theoretical discourse. Since, however, with Kant and contrary to the Cartesian tradition, Sellars viewed sensations as *non*-intentional items, his account both of their place within the manifest image and their ultimate relocation within the scientific image differs essentially from his ontologically noncommittal functionalist picture of occurrent thoughts. Sellars proposed that it is the job of analogical thinking to construct new forms of concepts pertaining to theoretical entities. Within the philosophically refined manifest image, sensation concepts pick out non-intentional states of individual perceivers, 'sensings', whose intrinsic characters are analogically indicated by adverbial transpositions of qualitative predicates of objects. In a series of essays stretching over a period of forty years and widely regarded as among his most difficult and challenging works, however, Sellars argued further that, because the manifest image's unitary perceiving subjects have ontological pluralities as their scientific image counterparts, the fusion of the two images at the point of sensations will in fact require the postulation of further (theoretically) basic entities which actually ontologically instantiate qualitative sensory contents conceived in yet another analogically constructed categorial guise distinct from both 'properties of objects' and 'manners of sensing'. In particular, he concluded, sensory contents can be non-epiphenomenally integrated into the scientific image only after it has as a whole been transposed from its classical 'thing-like' (particulate) form into a categorially monistic framework all of whose fundamental entities are 'event-like' absolute processes (see Mental states, adverbial theory of; Epiphenomenalism; Qualia).

3 Epistemological perspectives

Sellars' key nominalistic strategies could succeed only if the notion of a linguistic item's having a semantic or inferential function could itself be explicated without recourse to irreducibly platonistic or mentalistic conceptions. One of the greatest strengths of his systematic philosophy is the exquisite care with which he proceeded to locate the normative conceptual order within the causal order and to interpret the modes of causality exercised by linguistic rules. For Sellars, inference itself is always a normative affair, a matter of the judgments one ought to or is entitled to make. He defuses the circularity which threatens such an account by arguing that our knowledge of what implies and follows from various claims is, in the first instance, a *practical* ability to discriminate, that is, to respond differentially to, good and bad inferences. Rule-governed linguistic behaviour develops out of multiple repertoires of 'pattern-governed behaviour', behaviour which exhibits a pattern because the propensity to produce behaviour belonging to that pattern has been selectively reinforced and contrary propensities selectively extinguished (see language, social nature of; Meaning and rule-following). The pattern-governed behaviour characteristic of language includes 'language-entry transitions', propensities to respond to non-linguistic states of affairs (such as sensory stimulations) with appropriate linguistic activity; 'language-departure transitions', propensities to respond to a subset of linguistic representings (for example, such first-person future-tensed conduct-ascriptions as 'I shall now raise my hand') with appropriate corresponding behaviour; and 'intra-linguistic moves', propensities to respond to linguistic representings with further linguistic episodes (only) in patterns corresponding to valid theoretical and practical inferences. Linguistic roles or functions, Sellars suggested, are ultimately individuated in terms of the structures of positive and negative uniformities generated in the natural order by such pattern-governed activities.

In the Kantian tradition Sellars insisted that, in contrast to the mere capacity to be sensorily affected by external objects, *perception* of how things are requires not only systematic differential response dispositions but also the ability to respond to sensory stimulation with a *judgment*, that is, the endorsement of a claim (see Perception, epistemic issues in). Sellars went on, however, to propose that reports of how things look or seem, rather than employing 'more primitive' concepts, result instead from withholding these characteristic endorsements. This account enabled him to explain the incorrigibility of 'seems' judgments that Cartesianism takes as its fundamental datum. Their incorrigibility is simply a matter of their tentativeness; a 'seems' judgment expresses a perceptual ascription without endorsing it. It follows that 'seems' judgments do not express a special class of immediate cognitions. Applying the concept 'looks red' requires the same mastery of inferential articulations, the same inferential 'know how', as does applying the concept 'is red'.

Sellars' analysis of the Cartesian incorrigibility of perceptual 'seemings' is one strand of the philosophical dialectic most frequently associated with his name, his comprehensive critique of the 'Myth of the Given'. Basic to this critique is his insistence on the irreducibly normative character of epistemic discourse. Characterizing an episode or state in epistemic terms is not giving an empirical description of it but rather placing it within a social framework of justifications, of having and being able to give reasons for what one says. All knowledge that something is the case - all 'subsumption of particulars under universals' - presupposes intersubjective learning and concept formation. It follows that the ability to be (epistemically) aware of a sort of thing rests upon a *prior* command of the concept of that sort of thing and cannot account for it - and this holds equally true for concepts pertaining to 'inner episodes'. The first-person reporting role of such concepts, a use Cartesians interpret as evidencing the 'privacy' of the mental and one's 'privileged access' to one's own mental states, is necessarily built upon and presupposes their intersubjective status.

The idea that a language necessarily contains a stratum of claims any of which, on various occasions, can occur either as a report (an unmediated causally evoked response) or as the conclusion of an inference (mediated by other linguistic-conceptual representations) suggests the possibility of a further stratum of purely inferential claims. That is how Sellars proposes that we understand theoretical claims, that is, as claims that one can *de facto* become entitled to endorse only as the conclusion of an inference. On this view, the difference between theoretical objects and observables is not ontological but methodological. It is not a matter of the kind of thing our claims are about; it is a matter of how we come to be entitled to make them - and, as our technological sophistication increases, this can change. Once it is recognized that there is no epistemically privileged stratum of judgments with which to respond to one's sensory environment, and that such a 'language-entry' response is what 'observation' is, it follows that nothing is in principle unobservable. Noninferential and purely inferential claims can both be about the same kind of object (see Observation).

Sellars' holistic view of justification implied that the reasonableness of accepting even first principles is a matter of the availability of good arguments warranting their acceptance. Since it is definitive of first principles that they cannot be derived by sound theoretical reasonings from still more basic premises, Sellars located the requisite arguments in a stratum of 'vindications', practical reasonings in which the adopting of specific principles (an epistemic conduct) is demonstrated to contribute to the realization of non-arbitrary epistemic ends. From the ontological point of view, however, such practical cognitions - intentions and volitions - are simply species of occurrent thinkings whose unique conduct-structuring functional role is to be understood in terms of their special ('language-exit') relationships to non-linguistic behaviour (see Justification, epistemic).

For Sellars, it is finally practical thinking which lies at the centre of the framework of persons as such (see Persons). To think of an entity as a person is to think of it as actually or potentially a member of a community, and it is the most general common intentions of a community - its 'we-intentions' - that fundamentally define the structure of norms and values, crucially including those which make meaningful discourse and rationality itself possible, in terms of which the conducts of its members come to be appraised. A genuinely synoptic vision of man-in-the-world, Sellars concluded, can therefore be achieved only by enriching the scientific image with the language of individual and shared intentions.

List of works

Sellars, W.S. (1963) *Science, Perception and Reality*, London and New York: Routledge & Kegan Paul; repr. Atascadero, CA: Ridgeview, 1991.(Contains Sellars' best-known essays, including his classical critique of the 'Myth of the Given', 'Empiricism and the Philosophy of Mind', and his metaphilosophical manifesto, 'Philosophy and the Scientific Image of Man'.)

Sellars, W.S. (1967) *Philosophical Perspectives*, Springfield, IL: Charles C. Thomas; repr. Atascadero, CA: Ridgeview, 1977, 2 vols.(Work from the 1950s and early 1960s. Part 1 consists of historical essays on Plato, Aristotle and the Rationalists. Part 2 includes important original essays in metaphysics and the philosophy of mind.)

Sellars, W.S. (1968) *Science and Metaphysics: Variations on Kantian Themes*, The John Locke Lectures for 1965-6, London and New York: Routledge & Kegan Paul; repr. Atascadero, CA: Ridgeview, 1992(Based on his John Locke Lectures for 1965-6. The most systematic presentation of Sellars' views on perception, intentionality, representation, truth and the metaphysics and ethics of persons, developed in relation to the work of Kant, Peirce and the early Wittgenstein.)

Sellars, W.S. (1974) *Essays in Philosophy and Its History*, Dordrecht: Reidel.(A rich collection of historical interpretive and systematic essays from Sellars' most productive years. Includes his presidential address to the American Philosophical Association on the Kantian text 'this I or he or it (the thing) which thinks…', as well as significant contributions to the philosophy of language, metaphysics and the philosophy of science.)

Sellars, W.S. (1980) *Naturalism and Ontology*, Atascadero, CA: Ridgeview.(Sellars' John Dewey Lectures for 1973-4 present his mature views on the interrelationships of language, logic and ontology. The most systematic defence of his 'linguistic nominalism'.)

Sellars, W.S. (1981a) *Pure Pragmatics and Possible Worlds*, ed. and with intro. by J.F. Sicha, Atascadero, CA: Ridgeview.(A comprehensive collection of Sellars' earliest works (1947-53). These richly textured and dialectically complex early essays are difficult to access, but, besides offering a developmental perspective on Sellars' overall corpus, they include a number of interesting ideas and theses not explicitly developed in his later work.)

Sellars, W.S. (1981b) 'Foundations for a Metaphysics of Pure Process', *Monist* 64: 3-90.(A special issue of the *Monist*, containing Sellars' Carus Lectures from 1977-8. This is the most developed and systematic presentation of Sellars' unique views in the philosophy of mind. The title reflects his conviction that sensible qualities can be satisfactorily accommodated within a naturalistic worldview only in the context of a (speculatively-envisioned) ontology of 'pure processes'.)

Sellars, W.S. (1989) *The Metaphysics of Epistemology: Lectures by Wilfrid Sellars*, ed. P.V. Amaral, Atascadero, CA: Ridgeview.(This posthumously published work reproduces a series of university lectures given by Sellars in 1975 on central topics in epistemology and metaphysics. In sharp contrast to his densely written essays, Sellars' classroom presentations tended to be discursively relaxed and informal. This charmingly illustrated book is consequently a good first introduction to his complex views regarding perception, knowledge, minds,

meaning and representation.)

Seibt, J. (1990) *Properties as Processes: A Synoptic Study of Wilfrid Sellars' Nominalism*, Atascadero, CA: Ridgeview.(The first full-scale, systematic, book-length study of Sellars' philosophy, written by one of his last doctoral students and described by Sellars himself as 'one of the best essays on my work that I have ever seen'. This presentation of Sellars as 'a unique example of radical and systematic nominalism' is indispensable for any serious student of his views.)

Semantic paradoxes and theories of truth

The Cretan philosopher Epimenides said that Cretans always lie. Assuming, for the sake of argument, the mendacity of all other statements by Cretans, we get a paradox: if what Epimenides said was true, it must have been a lie, whereas if what he said was a lie, it would have made his statement true. The citizens of Crete have long since forgiven the insult, but semantics has never recovered.

Alfred Tarski perceived the consequences of Epimenides' paradox with particular clarity. Our common-sense intuitions about truth follow the paradigm: 'Snow is white' is true if and only if snow is white. As Tarski rigorously shows, if the language we are describing (the object language) is the same as the language in which we are formulating our theory (the metalanguage), this paradigm will be inconsistent with the rudimentary laws of syntax. The conclusion Tarski drew was that, if we are to develop a satisfactory theory of truth, our metalanguage must be essentially richer in expressive power than the object language. Since there is no human language essentially richer than English (or any other natural language), there can be no satisfactory theory of truth for English.

One earnestly hopes that this is not the end of the matter. Tarski's analysis leaves open the prospect that we can develop a fully satisfactory theory of truth for a substantial fragment of English; also the prospect that we can develop a theory of truth for English as a whole which, while not fully satisfying our intuitions, is none the less useful and illuminating.

Both prospects have been substantially advanced by Saul Kripke's 'Outline of a Theory of Truth', *which exploits the idea that there are truth-value gaps, statements which are neither true nor false, and that Epimenides' insult was one of them.*

Invocation of truth-value gaps does not resolve the paradox in any straightforward way. If we let the phrase 'the simple liar sentence' refer to the sentence 'The simple liar sentence is false', we see that we can readily account for the paradoxical features of the sentence by declaring the sentence neither true nor false; but if we let the strengthened liar sentence be 'The strengthened liar sentence is not true', we get a sentence we cannot dispose of so tidily. If the strengthened liar is neither true nor false, then it is not true; but that it is not true is precisely what the sentence says.

Truth-value gaps have not vanquished the liar paradox. Nor have any of the alternatives, the most prominent of which are a contextualist account, which sees the English word 'true' as radically ambiguous, and so-called 'revision theory', which investigates the cyclic reasoning that occurs when we try to evaluate the simple liar sentence: if the sentence is true, then it must be false; but if, then, it is false, it must be true; and so on. While these approaches have not eliminated the paradox, they have opened new approaches that have greatly improved our prospects for finding a comfortable way to live with it.

1 Tarski's requirement of a richer metalanguage

Kurt Gödel (1931) proved the incompleteness of a version of Peano Arithmetic by associating a code number, denoted $\ulcorner\phi\urcorner$, with each sentence ϕ of the language of arithmetic, then constructing a sentence χ which denied that $\ulcorner\chi\urcorner$ was the code of a theorem (see Gödel's theorems). Tarski (1935) used Gödel's construction to give a formalized version of the liar paradox. If $Tr(x)$ were a formula of the language of arithmetic which represented the set of code numbers of true sentences, we would expect to have

$$Tr(\ulcorner\phi\urcorner) \leftrightarrow \phi(\mathrm{T})$$

for each sentence ϕ. But Gödel's methods can be used to construct a sentence λ such that $\lambda \leftrightarrow \neg Tr(\ulcorner\lambda\urcorner)$ is a theorem. We conclude that there is no formula of the language of arithmetic which represents the set of code numbers of true sentences of the language of arithmetic. Indeed, this result holds not only for the language of arithmetic but for any language which includes the language of arithmetic.

Arithmetic plays an inessential role here. Quine (1946) shows that we can encode the language of arithmetic into any language which can provide a rudimentary theory of syntax. We are forced to conclude that, if $\mathcal{L}$ is a language that is able to describe its own syntax, then there is no open sentence $Tr(x)$ of $\mathcal{L}$ such that the schema (T) is consistent with the laws of syntax; here $\ulcorner\phi\urcorner$ is a standard name of ϕ which describes the sentence in terms of its

syntactic structure. On the other hand, any semantic theory which adequately represents our intuitive understanding of truth must surely imply all the (T)-sentences. We conclude that there is no possibility, consistent with the laws of syntax, of finding an open sentence of $\mathcal{L}$ which adequately represents the set of truths of $\mathcal{L}$. The conclusion Tarski drew, and which nearly everyone has accepted, is that, to develop a satisfactory theory of truth for $\mathcal{L}$ we must work within a metalanguage richer than $\mathcal{L}$ in expressive power.

2 *Principia Mathematica* and its successors

Whitehead and Russell responded to Epimenides' paradox by proposing a layered multiplicity of notions of truth. Simple statements of fact enjoy the first order of truth; attributions of truth at order one will be true or false at order two; and so on. An attribution of *n*th order truth must always have order higher than *n*. In this way (though they did not give details), Whitehead and Russell were able to develop the semantics of *Principia Mathematica* without contradictions. *Principia Mathematica* was designed to resolve a variety of paradoxes in addition to the liar. Here we shall follow contemporary practice in separating the semantic from the set-theoretic paradoxes (as recommended by Ramsey 1925), and in focusing on the liar as our paradigmatic representative of the former.

Tarski's approach to the liar was similar to Whitehead and Russell's, but simplified from the intricacies of the theory of types. Tarski spoke of a hierarchy of languages. The ground language has no semantic predicates, while the $(n+1)$th language is derived from the *n*th language by adding a predicate true_n whose extension is the true sentences of the *n*th language.

Whitehead and Russell proposed to apply their analysis to natural languages by treating the English word 'true' as ambiguous; contradictions arise from failing to recognize the ambiguity.

Their proposal has been vigorously pursued, by Tyler Burge (1979), Charles Parsons (1974), Jon Barwise and John Etchemendy (1987) and others, who have treated 'true' as an indexical term, like 'here' and 'now', whose extension is determined in part by the context of utterance. If everything Plato says is either true_{12} or false_{12}, the use of 'true' in 'Everything Plato says is true' will be contextually determined to mean 'true_{13}'. One quickly requires transfinite indices, going beyond the finite levels of *Principia Mathematica*.

Paradoxes arise when the customary rules for placing subscripts falter. Ordinarily, the subscript taken by 'false' in the sentence 'Everything a Cretan says is false' will be greater than the subscripts supplied to any occurrence of 'true' or 'false' in any utterance by a Cretan. But it is not possible to observe this rule when the sentence is uttered by a Cretan. If we take the word 'false' in Epimenides' statement 'Everything a Cretan says is false' to mean 'false_α', we find that his statement is neither true_α nor false_α, since the predicates 'true_α' and 'false_α' only apply to sentences with subscripts less than α.

From a higher level of reflection of which Epimenides himself was in principle incapable, we can see that, since Epimenides' statement that everything a Cretan says is false_α is not false_α, we can make out a sense in which the sentence 'Everything a Cretan says is false' is false, namely, 'Everything a Cretan says is false_α' is $\mathrm{false}_{\alpha+1}$. We should not say, however, that what Epimenides said was false after all, rather, the sentence Epimenides uttered expresses something false when we say it, though in Epimenides' mouth it was neither true nor false.

Talk of levels of reflection is something the theorist engages in when describing the language, but not something speakers of the language engage in. If this were not so, Epimenides could say 'Nothing a Cretan says is true at any level of reflection' and reinstate the paradox. Thus we still submit to Tarski's requirement that the metalanguage have expressive powers not available in the object language. Again, the theorist can make the subscripts under 'true' and 'false' explicit, and use variables as subscripts. The speakers of the language cannot do this, otherwise they could get a contradiction by formulating the explicit liar ('The explicit liar is not true_α, for any α'). Contextualists have not overturned Tarski's requirement that the semantics of a language be developed in a richer metalanguage, nor, for the most part, have they attempted to do so. Instead they have tried to show that, contrary to first impressions, Tarski's requirement is relaxed enough to make room for virtually everything speakers of English want to say.

3 Kripke's theory of truth

We have been pretending that, apart from one notorious remark by Epimenides, everything ever said by a Cretan is

outright false. This pretence is, of course, contrary to fact, and, once we drop the pretence, Epimenides' statement is no longer problematic. If we hear a Cretan remark that snow is white, we can conclude at once that not all Cretans always lie, hence Epimenides' statement is false. To reach this judgment, it is not necessary to examine everything a Cretan has ever said; it is enough to find one Cretan truth.

The assignment of levels we get from *Principia Mathematica* is unnecessarily extravagant. It is based upon the idea that, to determine the truth of 'Everything a Cretan says is false', we need to take account of everything any Cretan ever says, so it tries, unsuccessfully, to assign to the sentence a level higher than the level assigned to any Cretan statement. But to determine that Epimenides' statement is false, we do not need to take account of everything a Cretan ever says, we only need to find one truth uttered by a Cretan. So, if some Cretan statement is true at the first level, we can declare Epimenides' statement false at the second level, without waiting to examine a raft of irrelevant further statements.

This adjustment in the assignment of levels effects a remarkable simplification and clarification of the hierarchical structure. In describing the construction, we shall utilize a first-order language with primitive connectives 'and', 'not' and 'all', other connectives defined as usual. All terms other than '*Tr*' are assumed already to have a fixed meaning. We assume that our universe of discourse is a set, and we suppose that every member of the universe is named by some constant, expanding the language if necessary to ensure this. (Alternatively, we could define truth in terms of satisfaction, as Tarski does; but this would complicate matters.) We assume that the language can describe its own syntax, either directly or via a Gödel coding.

A non-semantic atomic sentence will be either true_0 or false_0.

A sentence of the form $Tr(c)$ is $\mathrm{true}_{\alpha+1}$ if *c* denotes a sentence which is true_α, and $\mathrm{false}_{\alpha+1}$ if *c* denotes a sentence which is false_α. If the individual denoted by *c* is not a sentence, $Tr(c)$ is false_0.

If ϕ is true_α and ψ is true_β, the conjunction $(\phi \wedge \psi)$ will be $\mathrm{true}_{\max(\alpha,\beta)}$. If either conjunct is false_γ for some γ, the conjunction is false_γ for the least such γ.

A negation is true_α if the negatum is false_α and false_α if the negatum is true_α.

A universally quantified sentence is true_α if α is the least ordinal such that every substitution instance of the sentence is true_β for some $\beta \leq \alpha$. If some substitution instance of $\psi(x)$ is false_γ, then $(\forall x)\psi(x)$ is false_γ for the least such γ.

Kripke's proposal (1975) is that a sentence be regarded as true if it is true_α for some α, false if it is false_α for some α, and undetermined otherwise. Applying his construction to a suitably regimented fragment of English, we find that it manages narrowly to skirt the edge of paradox without falling into contradiction, and the truth-values it supplies, when it supplies truth-values, are invariably the intuitively correct ones. For example, suppose that Socrates says only

Everything Plato says is true.

while Plato says

Not everything Socrates says is true.
Everything Epimenides says is true.

and Epimenides says

Nothing a Cretan says is true.
Snow is white.

Epimenides' second statement is true_0, so his first statement is false_1. Hence Plato's second statement is false_2, Socrates' statement is false_3, and Plato's first statement is true_4.

Not only does Kripke's theory get the right truth-values, but, more importantly, it explains them. Sentences declared true are true because they are grounded in the non-semantic facts. Thus a sentence is true_α for some α just in case it is derivable from true atomic and negated atomic non-semantic sentences by the following rules,

while a sentence is false_α, for some α, just in case its negation is derivable:

'*Tr*'-introduction: If *c* denotes a sentence ϕ, infer $Tr(c)$ from ϕ.
'$\neg Tr$'-introduction: If *c* denotes a sentence ϕ, infer $\neg Tr(c)$ from $\neg\phi$. Also, if *c* denotes a non-sentence, you may write $\neg Tr(c)$.
Conjunction introduction: Infer a conjunction from its conjuncts.
Negated conjunction introduction: Infer the negation of a conjunction from the negation of either conjunct.
Double negation introduction: From a sentence, infer the negation of its negation.
Universal quantification introduction: Infer a universal quantified statement from all of its instances. (This is an infinitary rule.)
Negated universal quantification introduction: Infer the negation of a universally quantified statement from the negation of any of its instances.

4 The fixed-point theorem

We have been speaking of 'true' as an ambiguous predicate. It is perhaps simpler, and certainly closer to Kripke's original way of thinking, instead to regard 'true' as a univocal predicate in a language with a nonclassical logic. We employ Kleene's 'strong three-valued logic' (see Kleene 1952: §54), according to which a predicate has an 'extension', consisting of those things to which it is determined that the predicate applies, and an 'anti-extension', consisting of those things to which it is determined that the predicate does not apply. The two cannot overlap, but there may be things to which it remains unsettled whether the predicate applies. An atomic sentence $Rc_1 \ldots c_n$ is true if the *n*-tuple consisting of the things denoted by c_1 to c_n lies in the extension of *R*, false if it lies in the anti-extension, and truth-valueless otherwise. A conjunction is true if both conjuncts are true and false if either conjunct is false. A negation is true if the negatum is false and false if the negatum is true. A universally quantified statement is true if every instance is true and false if at least one instance is false.

In the application we are interested in, all the terms other than '*Tr*' already have a fixed interpretation in which the anti-extension is the complement of the extension, so all we need to determine is the extension and the anti-extension of '*Tr*'. Where *A* and *B* are non-overlapping sets, let $\Gamma(A, B)$ be the pair $\langle C, D\rangle$, where *C* is the set of sentences which are declared true if *A* is assigned as the extension of '*Tr*' and *B* as its anti-extension; and *D* is the union of the set of non-sentences and the set of sentences declared false when *A* is assigned as the extension of '*Tr*' and *B* as its anti-extension. $\langle A, B\rangle$ is a 'fixed point' if and only if $\langle A, B\rangle = \Gamma(A, B)$.

Kripke's construction can now be succinctly characterized. Let *C* be the set of sentences which are true_α for some α, and let *D* be the set consisting of the non-sentences and the sentences which are false_α for some α. Then $\langle C, D\rangle$ is the smallest fixed point; that is, it is a fixed point included in every other fixed point. (We say $\langle A, B\rangle$ is included in $\langle C, D\rangle$ if $A \subseteq C$ and $B \subseteq D$.)

The existence of fixed points is startling. The liar paradox shows that, within the context of classical two-valued logic, it is not possible to assign an extension to '*Tr*' in such a way that, for any sentence ϕ, ϕ is true or false according as $Tr(\ulcorner\phi\urcorner)$ is true or false. We can, however, solve the analogous problem for three-valued logic. At a fixed point, we assign an extension and an anti-extension to '*Tr*' in such a way that, for any sentence ϕ, ϕ is true, false or unsettled according as $Tr(\ulcorner\phi\urcorner)$ is true, false or undecided.

There are fixed points other than the smallest. If *A* and *B* are non-overlapping sets with $\langle A, B\rangle \subseteq \Gamma(A, B)$, then there is a smallest fixed point which contains $\langle A, B\rangle$. The extension of '*Tr*' in this smallest fixed point consists of the sentences which are derivable from the true atomic and negated atomic non-semantic sentences, together with the sentences in *A* and the negations of the sentences in *B*.

Fixed points other than the smallest are useful in describing the different sorts of pathological behaviour we find among self-referring sentences. Tarski's sentence λ, which asserts its own untruth, is viciously paradoxical; whether we declare it true or false, we fall into contradiction (see Gödel's theorems). By contrast, if we formalize the construction of the truth-teller sentence ('The truth-teller sentence is true'), getting a sentence τ which is provably equivalent to $Tr(\ulcorner\tau\urcorner)$, we again get a sentence which is paradoxical, but in a more compliant fashion; whether we declare the sentence true or false, the sentence is amiably willing to go along, but no such classification has any basis in extra-semantic reality.

The difference between these two sorts of pathologies is reflected in the structure of the fixed points. There are no fixed points in which λ is assigned a truth-value. By contrast, there are some fixed points in which τ is true, others in which it is false, and still others in which it lacks a truth-value.

There are a great many fixed points; if the language has κ sentences, there will be 2^κ of them. The fixed points constitute a complete lower semi-lattice, that is, a partially ordered set in which every non-empty subset has a greatest lower bound. If $\mathcal{K}$ is a non-empty collection of fixed points, the union of all the fixed points which are included in every member of $\mathcal{K}$ will be a fixed point, so it will be the greatest lower bound of $\mathcal{K}$.

5 Classical-logic versions of Kripke's theory

Where Kripke's construction assigns a truth-value, the value it assigns invariably agrees with our intuitive understanding of the everyday application of 'true'. However, there are many sentences to which the construction fails to assign a truth-value but about which ordinary intuition fails to detect even a whiff of paradox. For example, 'A conjunction is true if both its conjuncts are true' is, according to intuition, harmlessly and obviously true, yet the construction fails to give it a truth-value. Indeed, the construction fails to provide even the simplest semantic generalizations, withholding its assent from such harmless platitudes as 'Every true sentence is a true sentence'; since $Tr(\ulcorner\lambda\urcorner)$ is truth-valueless, so is $(Tr(\ulcorner\lambda\urcorner) \rightarrow Tr(\ulcorner\lambda\urcorner))$, hence $(\forall x)(Tr(x) \rightarrow Tr(x))$ falls into the gap between truth and falsity.

This limitation is easily remedied by extending the rules of inference to encompass classical logic and taking as axiomatic the principle that, if a conditional and its antecedent are both true, the consequent is also true. Thus the variant construction treats a sentence as true just in case it is derivable from true atomic and negated atomic non-semantic sentences, together with instances of the schema

$$(Tr(\ulcorner\phi \rightarrow \psi\urcorner) \rightarrow (Tr(\ulcorner\phi\urcorner) \rightarrow Tr(\ulcorner\psi\urcorner))),$$

by '*Tr*'-introduction, '$\neg Tr$'-introduction, universal quantification introduction, and the laws of classical logic.

According to this variant construction, all classically valid sentences are true, in particular, $(\forall x)(Tr(x) \rightarrow Tr(x))$. For each ϕ and ψ, the conditional

$$((Tr(\ulcorner\phi\urcorner) \wedge Tr(\ulcorner\psi\urcorner)) \rightarrow Tr(\ulcorner\phi \wedge \psi\urcorner))$$

is derivable from the fact that '*Tr*' distributes over conditionals, and the generalization that a conjunction is true if both its conjuncts are true follows by universal quantification introduction. Indeed, we can show that an inference schema is valid in classical logic if and only if all substitution instances of the schema are truth-preserving.

There is a price to pay. In the original construction, truth is unmistakably grounded in the non-semantic facts. In the alternative construction, this is not so evident, since we want an explanation of the truth of the laws of classical logic. In the original construction, the truth of a disjunction was based upon the truth of one of its disjuncts, but, in the alternative construction, this is no longer so.

Another construction with much the same effect employs Bas van Fraassen's method of 'supervaluations' (1966) in place of Kleene's three-valued logic; this is the method suggested by Kripke himself. The sentences declared true in $\Gamma(A, B)$ will be those sentences true in all the classical models we get from the original model by taking the extension of '*Tr*' to be a consistent set of sentences, closed under first-order consequence, which contains *A* and is disjoint from *B*; the sentences declared false will be those whose negations are declared true. A sentence is regarded as true if it is declared true in the smallest fixed point.

The two constructions give similar results. Indeed, if the language is countable (which implies, since everything has a name, that the universe of discourse is countable), they give precisely the same results.

The classical-logic versions of Kripke's theory capture a great many of our common-sense intuitions about truth and paradox, but there remain fundamental intuitions that they leave aside. Notably, the intuition driving the theory is that the paradoxical sentences are neither true nor false. But the statement that the strengthened liar sentence is neither true nor false, while formalizable in the language, is never accepted as true. That the strengthened liar sentence is neither true nor false is something we can only see from the perspective of an essentially richer metalanguage. Within the object language, we can only recognize a sentence as untrue if at some

stage it is declared false; only from the external vantage point of the metalanguage can we regard a sentence as untrue because it is never declared true.

6 Revision theory

There are other proposals for obtaining an unambiguous truth predicate within a classical framework, notably the ‘revision theory’ of Hans Herzberger (1982), Anil Gupta (1982) and Nuel Belnap (1982), which sees the paradoxes as arising because the processes by which we ordinarily introduce new terms into the language, as seen in ordinary explicit definitions and in inductive definitions, partially break down when the (T)-sentences are taken to define ‘*Tr*’. The processes fail to stabilize upon a single choice for the extension of ‘*Tr*’. Instead, if V_0 is a candidate for the extension of ‘*Tr*’ we get another candidate, at least as good, by taking the extension of ‘*Tr*’ to be the set V_1 of sentences true in the classical model obtained by setting the extension of ‘*Tr*’ equal to V_0. We get another good candidate by taking the extension of ‘*Tr*’ to be the set V_2 of sentences true in the model in which the extension of ‘*Tr*’ is V_1. The process never settles down. Whereas Plato’s first statement above is in V_n for all $n > 5$, if the simple liar sentence is in V_n, it is outside V_{n+1}, but it is back inside V_{n+2}. The process continues into the transfinite, and, as it proceeds, we get better and better candidates for the extension of ‘*Tr*’. The process must eventually repeat itself, and, after it starts to do so, the candidates we get are all optimal candidates for the extension of ‘*Tr*’. Because the starting point V_0 was arbitrary, there are many different revision sequences. Count a sentence as ‘stably true’ if there is an ordinal level after which it always appears at every stage in every revision sequence.

The details of extending the process into the transfinite - what exactly to do at limit stages - is a matter of some disagreement among the three authors mentioned above, but all agree that a sentence is in V_λ, for λ a limit, if it is in all V_α, for α a sufficiently large ordinal less then λ, and a sentence is outside V_λ if it is outside V_α for sufficiently large $\alpha < \lambda$.

Revision theory still requires a richer metalanguage. We can only construct the revision sequences when the universe of discourse of the original language is a set, so we cannot carry out the construction for the language of set theory or for English, languages whose universe of discourse is not a set. (In those languages, we can talk about all sets, and there is no set that includes all sets.) The hope is that, in spite of this limitation, the fragments of English amenable to revision-theoretic treatment will be rich enough so that their study will cast a useful light upon our ordinary conception of truth in English.

7 English as an object language?

Most of the recent work on the paradoxes has been aimed at explicating the intuitions that govern ordinary speakers’ usage of the word ‘true’. For such purposes, a theory which only takes account of a fragment of the natural language may well suffice. For some theoretical purposes, however, one would like a global semantic theory, which takes full account of the linguistic practices of English speakers. Should it turn out, on the contrary, that a comprehensive theory of language is inherently impossible, so that part of our language lies irretrievably beyond the reach of linguistic inquiry, this would severely curtail the hopes of science, and it would also gravely undermine the prevalent mood of metaphysical naturalism, according to which human language is a part of the natural order, not intrinsically more mysterious or less comprehensible than the planetary orbits.

Hopes for a comprehensive theory are greatly discouraged by the liar paradox, but, if our optimism persists, we have only two alternatives: either to restrict classical logic or to restrict schema (T) (see §1 above). Restricting the logic does not seem to help. If we replace classical logic with Kleene’s three-valued logic, we still do not get the (T)-sentences. Indeed, Feferman’s investigations (1984) would seem to show that we do not get the (T)-sentences within any reasonable logic.

We might hope to preserve at least one direction of schema (T), but even here our hopes are thwarted by Montague’s theorem (1963) that any logical system that includes the left-to-right direction of (T) together with the ‘*Tr*’-introduction rule will be inconsistent with the laws of syntax. A dual result shows that the right-to-left direction is incompatible with ‘$\neg Tr$’-introduction and also that it is incompatible with ‘Tr’-elimination, which is the converse of ‘*Tr*’-introduction.

Another possibility, recommended by Vann McGee (1991), is to replace schema (T) with a system of rules of

inference: 'Tr'-introduction and -elimination and ' $\neg Tr$'-introduction and -elimination. The paradoxes are diagnosed as arising from the misapplication of these rules of inference within conditional proofs. The classical-logic versions of Kripke's theory can be employed to show that this system of rules is consistent.

As this consistency proof shows, Kripke's construction is a highly versatile tool, which can be usefully applied to a wide variety of philosophical purposes.

Semantics

Semantics is the systematic study of meaning. Current work in this field builds on the work of logicians and linguists as well as of philosophers. Philosophers are interested in foundational issues in semantics because these speak to the nature of meaning, as it embeds in our thinking and in our relations to each other and to the world. Of special interest are questions about how a semantic theory should respect the connections of meaning to truth and to understanding. In addition, numerous semantic problems concerning particular linguistic constructions bear philosophical interest, sometimes because the problems are important to resolving foundational semantical issues, sometimes because philosophical problems of independent interest are expressed using the constructions, and sometimes because clarity about the semantic function of the constructions enables clarity in the development of philosophical theories and analyses.

1 Historical sources and goals

Systematic theorizing about meaning in language always has been of philosophical interest. In addition to being a science with interesting foundational problems, semantics interests philosophers because of their special interests in the nature of meaning and in the meaning of particular sorts of language, notably the language that serves as our primary means of expressing philosophically interesting concepts and thoughts (see Language, philosophy of).

Contemporary semantics owes a great deal to work in formal logic by Gottlob Frege, Bertrand Russell and Alfred Tarski, among others (see Logic, philosophy of). This work has provided techniques for constructing *formal systems* - abstract systems of symbols and sets with rigorously defined logical and structural relationships (see Formal languages and systems). Ludwig Wittgenstein and logical positivists such as Rudolf Carnap found these techniques so compelling that they took certain formal, logical systems to reveal the kind of structure that any coherent language - in particular, any language suited to serious science - must possess at its roots (see Logical positivism). A less extreme but more enduring view is that many aspects of natural languages are aptly *modelled* by formal systems - whether formal systems devised independently by logicians or designed expressly to reveal the systematic structure of the languages in question.

Recently, semantics has profited from the development, under the aegis of Noam Chomsky, of systematic accounts of natural language syntax (see Syntax). Chomsky regards the grammar of a person's language as a partly innate theory that is implicitly mastered in acquiring the language (see Language, innateness of). The linguist's task is to make this theory explicit, guided by the person's spontaneous judgments about which constructions are grammatically acceptable, by experimental evidence about their cognitive faculties, and by general evidence about innate constraints on human grammars. Armed with this conception of the linguist's task, Chomsky and others have developed powerfully sophisticated theories of natural language grammar. Contemporary semanticists find this work useful for a number of reasons. Many semanticists now view their task in a Chomskian light: to uncover partly innate, cognitively real theories. Also, most contemporary semantical theories begin with something very like a grammar: a systematic account of the way sentences of the language in question are constructed from their meaningful parts - and it is quite reasonable to expect that the semantically relevant kind of sentence-structure bears a close relation to the correct grammar for the language.

2 Contemporary semantical traditions

The meaning of a statement is a matter of how things are, according to the statement; and the meaning of any expression is what users attach to it in their competent understanding of it. Semantics, then, ought to respect the outward-looking aspect of meaning: meaning fixes the representational and descriptive powers of language. And semantics must also respect the cognitive and epistemological aspect of meaning: meaning is cognized - it is grasped, known, understood.

A language (whether it be a shared social entity such as English, a narrower dialect, or even an individual's own 'idiolect') contains reusable words and expressions such as words and sentences. These are called expression-types because different tokenings of the expressions (different utterances or inscriptions of them) are importantly similar - they are of the same type (see Type/token distinction). Expression-types in a language have 'timeless' meaning that is drawn on in the various tokenings of the expressions. However, meanings can be expressed in the tokenings

that complete, or go beyond, the timeless meanings of the expressions used. For instance, a particular utterance of the sentence ‘That was worse’ would express a meaning to do with a particular subject matter (‘that’) and would involve (because of ‘was worse’) a gesture to another subject matter and to a dimension of evaluation. An attractive principle is that the timeless meaning of an expression simply is a matter of the expression’s distinctive potential for expressing meanings in particular tokenings. The discipline of pragmatics (whose border with semantics is notoriously porous) seeks to understand the relations between the timeless meaning of expression-types and the meanings achieved by tokenings, as well as the variety of ways tokenings (or speech acts) can achieve communicative and other purposes (see Pragmatics; Presupposition; Propositions, sentences and statements; Speech acts).

A fact about natural languages that is no less impressive for being obvious is that every natural language issues in infinitely many sentences with different meanings. In English, ‘Ann ate a pear’ differs in meaning from ‘Ann ate a pear, and then Ann ate a pear’, which differs too from ‘Ann ate pear, and then Ann ate a pear, and then Ann ate a pear’, and so on. Any acceptable semantic account of a natural language will reveal its meanings as depending systematically on its repeatable, recombinant features (features of its expression-types and of their tokenings). One way to accomplish this is to show how meanings of complex expressions are generated from the meanings of simpler expressions, according to how the simpler expressions are combined. Such a strategy might employ a notion of *semantic values* of the meanings that are assigned to the simpler expressions (or tokenings) in the generation of the meanings of the more complex. That structure of a linguistic expression which, on these accounts, provides the key to the compositional derivation of its meaning sometimes is called the expression’s *logical form*, because of assumptions about the nature of meaning to which we now turn (see Compositionality; Logical form).

The representational side of meaning has led many semanticists to take as their primary goal systematic accounts of the *truth-conditions* of sentences, as well as accounts of such related phenomena as the conditions of true application of predicates (such as ‘is a horse’) and the conditions of the denotation or reference of various noun phrases (such as proper names, definite descriptions like ‘the last Tsar’, and demonstratives like ‘this’). It is immediately plausible that conditions of truth, applicability and reference are proper subjects for a semantic theory. For instance, the meaning of ‘is a felucca’, very plausibly, is a matter of what it is for a thing to be a felucca, which, again plausibly, is given by revealing what it takes for a thing to be truly described as a ‘felucca’. Similarly, the meaning of ‘In Syracuse there are many feluccas’ is elucidated by characterizing how things would have to be to be truly so described (see Meaning and truth).

Because of the widespread view that a complete semantic account of a language must include systematic explanations of what it takes for its expressions to be true, to refer, or to apply truly, the central foundational issues in semantics include the nature of truth and reference, as well as the proper explanation and use within a semantic theory of the notions of truth- and applicability-conditions. Since truth- and application-conditions stand to each other in logical relations such as consistency and entailment, accounts of these conditions can serve what is regarded as another important goal in semantics: to explain the logical relations among linguistic expressions (and among their tokenings) (see Truth, coherence theory of; Truth, correspondence theory of; Truth, deflationary theories of; Truth, pragmatic theory of; Semantic paradoxes and theories of truth; Reference; Sense and reference).

A style of contemporary semantics that can be traced to Frege and Russell employs as semantic values abstract ‘universals’ such as *propositions* and *properties* - entities that embody truth- or application-conditions, in that (unlike linguistic expressions) they are not intrinsically tied to any particular language and have their truth- or application-conditions timelessly and essentially. Thus, some semantical frameworks start with conceptions of the nature of propositions and properties; within these frameworks the principal task in giving a semantical description of a given language is to discover the principles governing which expression-tokenings have as their semantic values which propositions and properties (see Propositions, sentences and statements; Universals; Intensional entities).

Some of these frameworks employ devices from the logical theory of models, in which the meanings of expressions are represented by set-theoretical structures (see Model theory). A particularly influential tradition in semantics deriving from the work of Carnap, Saul Kripke and Richard Montague, uses or imitates the notion of a ‘possible world’: the meaning of a statement is given by the sets of possibilities it excludes and allows, and the

meanings of smaller expressions are their contributions to this semantic function of the sentences in which they figure (see Semantics, possible worlds; Carnap, R.; Montague, R.M.; Kripke, S.A.; Semantics, situation). Among the philosophical insights claimed for this work is the idea that in addition to revealing a statement's simple truth-condition (the condition that the utterance must meet if it is to be true), a semantical theory ought further to reveal its *modal content*, which determines what sorts of possible situation the utterance correctly describes. Focus on this distinction has promoted intense debate about metaphysical necessity and possibility, in particular, on whether certain devices of natural language (such as proper names) presuppose substantive views about necessity and essence, and on whether these views are seriously tenable (see Proper names; Essentialism; Kripke, S.A.).

A somewhat different tradition in semantics has been pioneered by Donald Davidson, employing techniques due to Tarski (see Tarski's definition of truth). The goal in offering a Davidsonian semantics for a given language is to find an appropriate 'truth theory', thought of as a deductive system whose axioms and rules issue in 'T-sentences' such as 'The sentence "Schnee ist weiss" is true if and only if snow is white'. An appropriate truth-theory will not only be correct and complete, but also will in some sense explain the language-user's competence by revealing what it is that the speaker knows in knowing the language (see Meaning and truth; Meaning and understanding §2).

Recently, too, philosophers, linguists and cognitive scientists have developed systematic semantic accounts based on algorithmic or procedural conceptions of meaning. These traditions borrow from the logical theory of proof (see Semantics, game-theoretic; Proof theory).

All semantical traditions, even those that focus heavily on truth-conditions, must aim as well at least for compatibility with satisfactory explanations of the cognitive/epistemological aspects of meaning, including understanding (see Meaning and understanding; Meaning and verification; Sense and reference). One strategy is to keep issues about understanding at a remove from detailed semantic theorizing, by viewing understanding as involved not so much in the nature of meaning as in the uses to which meaning is put in thought and communication. David Lewis, for instance, proposes that a semantic account of a language is simply a correct description of the abstract function that assigns to statements in the language sets of possible worlds as meanings; understanding enters the picture only when we consider what constitutes the language's actually being used. For Lewis, the competent use of a particular language amounts to participation in a certain sort of conventional practice (see Language, conventionality of; Lewis, D.K.). Other strategies take semantic theorizing to be more directly focused on what the competent understanding of a language consists in. Some accounts in the Davidsonian tradition, for instance, submit truth-theories to constraints of cognitive plausibility: a truth-theory must not employ conceptual resources beyond those plausibly required of a competent language-user. Other accounts allow alien concepts in a semantic description of a language and employ a notion of *tacit knowledge* to explain how the semantic description represents what the language-user knows (see Knowledge, tacit). Also heavily cognitive in orientation are accounts within the Chomskian paradigm; these take the primary goal of semantics to be the discovery of the cognitive capacities and structures underlying linguistic competence (see Chomsky, N.). Some semantic accounts take as their task the explanation of how linguistic meaning is fixed by the meaning of mental items such as concepts and thoughts; for the ultimate source of meaning, these accounts defer to theories of cognitive semantics (see Mind, philosophy of; Grice, H.P.; Communication and intention; Concepts; Language of thought; Semantics, conceptual role; Semantics, informational; Semantics, teleological).

3 Issues and problems in semantics

Some debates about the semantic features of particular sorts of expression arise only within particular semantic traditions. Questions of *reference*, in contrast, are of very broad interest, since reference is widely taken to be a semantically central notion. Philosophers have hotly pursued questions about the nature of reference, about the proper role of reference in semantic theories and about how the reference of particular kinds of linguistic item is determined (see Reference; Sense and reference). Receiving special attention have been proper names, natural kind terms (like 'tiger' and 'gold'), context-dependent terms (such as the demonstrative 'that' and the indexical 'today') and theoretical terms of science (such as 'mass' and 'oxygen') (see Proper names; Natural kinds; Demonstratives and indexicals; Scientific realism and antirealism). Among the questions under heavy discussion are the extent to which the determinants of reference are settled by intrinsic features of a speaker's cognition, rather than being settled by features of the speaker's society and environment (see Language, social nature of; Content: wide and

narrow; Methodological individualism).

Issues about the semantical or logical structure of various locutions, in contrast, are often discussed in the context of particular traditions of semantic theory (see Logical form). Still, a number of such issues have interest that is not confined to any one semantic tradition. Among these are the proper treatment of definite descriptions such as ‘the short spy’. Definite descriptions resist easy assimilation either to the paradigm of proper names or to that of quantifying phrases such as ‘all circles’ and ‘three dogs’ (see Descriptions; Quantifiers). Also of persisting interest is the behaviour of ‘anaphoric’ pronouns - ones which in one way or another ‘refer back’ (or even ahead) - such as occur in ‘The dog is happy; he is wagging his tail’ and ‘Probably some dogs can climb trees; it is likely that they are small’. Difficulties in providing systematic explanations of the roles of anaphoric pronouns has led to a number of theories according to which semantic accounts of sentences must view their semantically relevant structure as inextricable from the larger discourse in which the sentences figure (see Discourse semantics; Anaphora). Even the logical form of apparently simple subject-predicate sentences has been debated. For instance, Davidson proposes that the logical form of ‘Bill is running’ involves not the simple predication of an attribute to Bill, but rather an existence claim about an event (perhaps: an event exists, which is a running, which is in progress, and of which Bill is the agent). This account is meant to cohere with a straightforward account of adverbs, in which, for instance, it is clear why ‘Bill is running’ is entailed by ‘Bill is running slowly’ (see Predication; Events; Adverbs).

So-called propositional-attitude ascribing statements (such as ‘Sue believes that oranges are expensive’) also have prompted extensive discussion. An ancient puzzle still has received no widely accepted solution: how is it that Hesperus and Phosphorus are one and the same entity, and yet ‘Hammurabi believed that Hesperus is bright’ might be true while ‘Hammurabi believed that Phosphorus is bright’ is false (see Propositional attitude statements; Indirect discourse; Intensionality)?

Another source of fascinating, but inconclusive, debate among semanticists is the treatment of conditionals (if/then sentences), including indicative conditionals like ‘If Oswald didn’t shoot Kennedy, then someone else did’ and subjunctive, counterfactual conditionals like ‘If Oswald hadn’t shot Kennedy, then someone else would have’. Concerning indicative conditionals, one current view is that their truth-conditions are aptly modelled on those of the material conditional of formal logic, while another is that indicative conditionals have no truth-conditions at all but only conditions of proper assertion (see Indicative conditionals). Counterfactual conditionals have been linked to metaphysical issues about necessity, causation and natural law, and debates about their interpretation are enmeshed with metaphysical debates (see Counterfactual conditionals).

Also among the issues that bear on semantic theories are questions about necessity and possibility, the nature and ontological acceptability of intensional entities, tense, metaphor, vagueness and language apparently about nonexistent and fictional entities (see Modal operators; Modal logic, philosophical issues in; Intensional logics; Intensional entities; Tense and temporal logic; Metaphor; Vagueness; Existence; Fiction, semantics of; Fictional entities; Necessary truth and convention).

Semantics, conceptual role

According to conceptual role semantics (CRS), the meaning of a representation is the role of that representation in the cognitive life of the agent, for example, in perception, thought and decision-making. It is an extension of the well-known 'use' theory of meaning, according to which the meaning of a word is its use in communication and, more generally, in social interaction. CRS supplements external use by including the role of a symbol inside *a computer or a brain. The uses appealed to are not just actual, but also counterfactual: not only what effects a thought* does *have, but what effects it* would *have had if stimuli or other states had differed. Of course, so defined, the functional role of a thought includes all sorts of causes and effects that are non-semantic, for example, perhaps happy thoughts can bolster one's immunity, promoting good health. Conceptual roles are functional roles minus such non-semantic causes and effects.*

The view has arisen separately in philosophy (where it is sometimes called 'inferential' or 'functional' role semantics) and in cognitive science (where it is sometimes called 'procedural semantics').

1 Motivations for CRS

There are two quite different projects that go by the name 'semantics'. One, which we might call *linguistic* semantics, deals with the meanings of particular expressions in particular languages and how they fit together to make up meanings of larger expressions. The second project, *metaphysical* semantics, is one of investigating the fundamental nature of meaning, especially what it is about a person that gives their words or thoughts whatever meanings they have in the first place. Conceptual role semantics (CRS) is in the domain of metaphysical semantics: it says that the nature of meaning is functional. It does not have anything very informative to say about linguistic issues, about particular languages or about how a language user works out the meanings of sentences on the basis of the meanings of their component words. But if correct, it can contribute to these enterprises by discouraging false and confused foundational views (see Semantics).

One major motivation for CRS is a functionalist approach to the mind generally (see Functionalism). Functionalism says that what makes a state a mental state and what gives a mental state the specific content that it has is the role it plays in interacting with other mental states in a creature's psychology.

This idea motivates a reply to theories that insist that a mind requires something more. For example, Searle (1980) has argued that computers cannot understand language in virtue of their programs or, more generally, by manipulating symbols in a certain way. He rests his case on a thought experiment, the Chinese room, in which a non-Chinese speaker manipulates Chinese symbols by following rules that do not require him to understand the meanings of the symbols he is manipulating. The rules are so devised that he produces sensible responses in Chinese to any Chinese inputs. Searle says that none the less he does not understand Chinese: he is just mindlessly manipulating symbols. CRS motivates the 'systems reply': if we can programme a computer to be intelligent, it will not be the central processing unit (CPU) all by itself that is intelligent or that understand the symbols, but rather all the complex relations between the CPU and other subsystems of the mind, for example, for perception, reasoning and decision making. So the whole system understands Chinese even if the person who is simulating the CPU does not (see Chinese room argument).

Approaching the matter from the point of view of language rather than thought, what makes CRS plausible is the fact that many terms seem definable only in conjunction with one another. For example, in learning the theoretical terms of Newtonian mechanics - 'force', 'mass', 'kinetic energy', 'momentum' and so on - we do not learn definitions outside the circle. There are no such definitions. We learn the terms by learning how to use them in our thought processes, especially in solving problems. Indeed, CRS explains the fact, noted by Thomas Kuhn (1962), that modern scientists cannot understand the phlogiston theory without learning elements of an old language that express the old concepts. The functional role of, for example, 'principle' as used by phlogiston theorists is very different from the functional role of any term or complex of terms of modern physics, and hence we must acquire some approximation of the eighteenth-century functional roles if we want to understand their ideas (see Definition; Scientific method).

Moreover, CRS does seem to give a plausible account of the meanings of the logical connectives. For example, we

could specify the meaning of ‘and’ by noting that certain inferences - for example, the inferences from ‘*p*’ and ‘*q*’ to ‘*p* and *q*’, and the inference from ‘*p* and *q*’ to ‘*p*’ - have a special status (they are ‘primitively compelling’, in the terminology of Peacocke 1992).

A further motivation for CRS is that it explains a reasonable version of a principle of charity according to which we cannot rationally attribute irrationality to a person without limit (see Charity, principle of §4). Attributing unexplainable irrationality leads to a poor match of roles. If the best translation yields poor enough matches, then the alien conceptual system is not intelligible in ours.

2 Two-factor CRS

Putnam (1975) raised what might seem to be a powerful objection to any CRS. He pointed out that many natural kind concepts, such as ‘water’ and ‘gold’, depend in part for their meaning upon something other than the role of a representation in a person’s head, namely upon what happens to be in their external environment (see Content: wide and narrow; Methodological individualism).

Some proponents of CRS have responded by favouring a ‘two-factor’ version of CRS. On this view, meaning consists of an internal, ‘narrow’ aspect of meaning - which might be handled by functional roles that are within the body - and an external referential/truth-theoretic aspect of meaning, which might be handled by some other metaphysical theories of meaning (for example, a causal one). According to the external factor, ‘Superman flies’ and ‘Clark Kent flies’ are semantically the same since Superman = Clark Kent; it is the internal factor that distinguishes them. But the internal factor counts ‘Water is more greenish than bluish’ as semantically the same in my mouth as in the mouth of my twin on twin earth (see Content: wide and narrow §2); in this case, it is the external factor that distinguishes them.

Two-factor theories gain some independent plausibility from the need for them to account for *indexical* thought and assertions, assertions whose truth depends upon facts about when and where they were made and by whom (see Content, indexical). For example, suppose that you and I say ‘I am ill’. One aspect of the meaning of ‘I’ is common to us, another aspect is different. What is the same is that our terms are both used according to the rule that they refer to the speaker; what is different is that the speakers are different. White (1982) generalized this distinction to apply to the internal and external factors for all referring expressions, not just indexicals.

In a two-factor account, the conceptual roles stop at the skin in sense and effector organs; they are ‘short-arm’ roles. But CRS can also be held in a one-factor version in which the conceptual roles reach out into the world - these roles are ‘long-arm’. Harman (1987) has advocated a one-factor account which includes in the long-arm roles much of the machinery that a two-factor theorist includes in the referential factor, but without any commitment to a separable narrow aspect of meaning.

3 Criticisms of CRS

Error. Actual conceptual roles involve errors, even dispositions to err. For instance, in applying the word ‘dog’ to candidate dogs, one will make errors, for example, in mistaking coyotes for dogs (see Fodor 1987). This problem arises in one form or another for all naturalistic theories of truth and reference, but in the case of CRS it applies to erroneous inferences as well as to erroneous applications of words to things. Among all the conceptual connections of a symbol with other symbols, or (in the case of long-arm roles) with the world, which ones are correct and which ones are errors? Saul Kripke (1982), for example, wonders what distinguishes someone who mistakenly says ‘ $57 + 65 = 5$’ from someone who says it correctly, meaning by ‘Čplus;’ a function that agrees with addition except in yielding a value of 5 with 57 and 65 as arguments. The answer a person gives in the two cases could be the same, correct in one and erroneous in the other.

Some think we can solve the problem by appealing to dispositions to ‘correct’ previous answers, or to ‘correct’ those corrections. But others wonder why all these dispositions could not be the same for two persons who use ‘Čplus;’ to designate different functions. (The problem of error is sometimes said to be the problem of specifying semantic ‘norms’, although norms in this sense should not be confused with norms in the sense of how one ought to apply a word; see Horwich 1994.) Another line of reply is to attempt to specify some sort of naturalistic idealization which specifies roles that abstract away from error, in the way that laws of free fall abstract away from friction.

Words/world. Fodor criticizes a computer-oriented form of CRS for confusing what words denote with the words themselves. The functional roles in the target version of CRS stress searching data banks and manipulating representations, and this Fodor says is like claiming that the meaning of ‘Napoleon won at Waterloo’ is a set of instructions for finding that sentence in a book in the New York Public Library. All such a search yields is more words: we never get the semantic values of those words, namely Napoleon or Waterloo. But, the CRS theorist says in response, long-arm roles include causal chains outside the machine. And the two-factor version of CRS relies on a second factor, the referential factor, to explain the relation between the word ‘Napoleon’ and Napoleon.

CRS is often criticized from the point of view of truth-conditional theories of meaning (see Meaning and truth). If the meaning of a sentence is its truth-conditions, then the meaning cannot be its conceptual role. But with the two-factor theory, proponents of CRS have the option of counting meanings as the same or different in accordance with whether the external factor specifies truth-conditions that are the same or different. Further, there is reason to suppose that meaning is more fine-grained than truth-conditions. For example, the truth-conditions of ‘I am happy’ and ‘Ned is happy’ are the same (since I am Ned), but the meanings of those sentences differ. The further machinery involved in the internal factor can capture the differences among sentences with the same truth-conditions.

Sensory properties. Fodor also criticizes CRS for giving the wrong account of how I and Helen Keller (who was blind and deaf from an early age) can mean the same thing by, for example, ‘Water tastes great’. After all, none of her thoughts bears the same relation to the evidence of sight and sound that mine do. But here Fodor assumes that CRS only has the resource of appealing to similarity in *inferential* role, which is entirely internal. He disparages such an account in favour of a referential view: we mean the same because our concepts of water are concepts of the same *thing*. But a two-factor CRS, relying in part on a referential component, has the option of giving exactly the same account as can a long-arm one-factor account.

What glues the two factors together. Fodor and Lepore (1992) object to the two-factor account, wondering what glues the two factors together. Why can there not be a sentence that has the inferential role of ‘Water is greenish’ but is true if and only if 3 is a prime number? But there is nothing in the CRS approach that dictates that there is any restriction at all on what roles can go with what truth-conditions. This is an independent question that both proponents and opponents of CRS can ask. Everyone who accepts the existence of inferential roles and truth-conditions should find the question meaningful, whether or not they think these are two factors of meaning.

4 Criticisms of CRS (cont.)

Holism. CRS is often viewed as essentially holistic, but the CRS theorist does have the option of regarding some proper subset of the functional roles in which an expression participates as the ones that constitute its meaning. Thus the subset could be taken to be those that are analytic (or ‘true by virtue of meaning’); or as the primitively compelling inferences (Peacocke 1992) plus those generated by them; or the explanatorily basic regularities (Horwich 1994).

One natural and common view of what distinguishes the meaning-constitutive roles is that they are analytic, or played by an expression by virtue of its meaning, as in the case of an inference from ‘bachelor’ to ‘male’. Proponents of CRS are thus viewed as having to choose between accepting holism and accepting that the distinction between the analytic and synthetic is scientifically respectable, a claim that has been seriously challenged by Quine (1954) (see Analyticity). Indeed, Fodor and Lepore (1992) argue that, lacking an analytic/synthetic distinction, CRS is committed to semantic holism, regarding the meaning of any expression as depending on its inferential relations to *every* other expression in the language (see Holism: mental and semantic). This, they argue, amounts to the denial of a psychologically viable account of meaning.

Proponents of CRS can counter as follows. First, there is a question of whether a meaning-constitutive inference is thereby analytic. *If* what is meaning-constitutive is analytic, then holistic versions of CRS need analyticity too, since they regard all inferences as meaning-constitutive. But if what is meaning-constitutive is *not* thereby analytic, then neither holistic nor non-holistic versions of CRS need analyticity. So analyticity is not the issue between holistic and non-holistic versions of CRS.

Second, proponents of CRS can reply that the view is not committed to regarding what is meaning-constitutive as

analytic. In terms of our earlier two-factor account, they can, for example, regard the meaning-constitutive roles as those that are explanatorily basic in a *narrow* psychology: they are the rules that explain other rules of use and determine *narrow* content (Horwich 1994). Narrow content does not involve *truth*-values; these arise only with regard to *wide* content, and so *a fortiori* it does not involve any commitment to *truth by virtue of meaning alone*.

A third approach to accommodating holism with a psychologically viable account of meaning is to substitute close enough similarity of meaning for strict identity of meaning. That may be all we need for making sense of psychological generalizations, interpersonal comparisons and the processes of reasoning and changing one's mind.

Compositionality. Fodor and Lepore (1992) raise a further worry that links the metaphysical semantic issue with a linguistic one: a CRS would seem to risk violating 'compositionality', that is, the requirement that the meaning of a complex expression be a function (in the mathematical sense) of the meanings of its parts (see Compositionality). It is widely thought that such a property of both language and thought is required to explain how human beings seem to able to grasp indefinitely many ever more complicated thoughts, and how they can learn to understand complex sentences on the basis of simple ones. CRS threatens this principle, since, Fodor and Lepore say, the conceptual role of a complex non-idiomatic representation is not always a function of the conceptual roles of its parts. Someone who thinks that rattling snakes, especially, are dangerous is disposed to infer 'This is dangerous' from 'This is a rattling snake' for reasons that may not depend at all on any inferences they are disposed to make from 'This is rattling' or 'This is a snake' separately.

Advocates of non-holistic versions of CRS should regard the argument's assumption that all inferences are to be included in inferential roles as question-begging. Non-holistic versions of CRS can deal with compositionality by counting only a subset of inferences as meaning-constitutive. As mentioned above, these inferences could be identified as the analytic ones, the explanatorily basic ones, or as those that are primitively compelling or generated by them. The threat to compositionality can be avoided by not counting the inference from 'This is a rattling snake' to 'This is dangerous' as part of the meaning-constitutive roles of either sentence.

Advocates of holistic versions of CRS may wish to go along with Fodor and Lepore in assuming that all inferences are part of inferential roles. They should point out that the inferential role of 'rattling' and 'snake' is a matter not just of their roles in *isolation* from one another, but also their roles in contexts involving 'rattling' and 'snake' *together*. The 'rules of use' of these terms are context-sensitive, not context-free.

Once we allow context-sensitive rules of use, compositionality can be trivially satisfied. For example, we can characterize the meaning of a word as an ordered pair, $\langle X, Y \rangle$, where *X* is the set of inferences *to* sentences containing the word and *Y* is the set of inferences *from* sentences containing the word. This is a holistic version of the view, for it includes the inference from 'rattling snake' to 'dangerous' in the meaning of 'rattling' and 'snake', and this example stands proxy for the inclusion of *every* inference in the meaning of every word involved in those inferences. Now the roles just mentioned satisfy the requirements of compositionality from a metaphysical point of view without being a psycholinguistic or a linguistic theory of the representations on the basis of which language is learned or sentences are understood.

5 Framework, not theory

CRS is more of a framework for a theory than an actual theory. There is no agreement among proponents of this framework about how the roles are constituted. By actual causal interactions among thoughts? All? Some? If some, which ones? And what about systematically mistaken inferences (for example, the 'gambler's fallacy')? Do widespread cognitive illusions contribute to the determination of meaning? Or are the roles normative? If the roles are idealized to avoid mistakes, how is the idealization supposed to be understood? Inference can be understood in intentional terms or in purely causal terms, and the latter would be preferable from the point of view of avoiding circularity in specifying roles. And is there any way to distinguish correcting an old practice from changing to a new one (Kripke 1982)? Many successful philosophical theories are quite sketchy. Some say that CRS is no worse than many of them, but others say that the problems in filling in these details involve difficulties that are fatal to the whole project.

Semantics, game-theoretic

Game-theoretic semantics (GTS) uses concepts from game theory to study how the truth and falsity of the sentences of a language depend upon the truth and falsity of the language's atomic sentences (or upon its sub-sentential expressions). Unlike the Tarskian method (which uses recursion clauses to determine satisfaction conditions for nonatomic sentences in terms of the satisfaction conditions of their component sentences, then defines truth in terms of satisfaction), GTS associates with each sentence its own semantic game played on sentences of the language. This game defines truth in terms of the existence of a winning strategy for one of the players involved. The structure of the game is determined by the sentence's structure, and thus the semantic properties of the sentence in question can be studied by attending to the properties of its game.

For each sentence *S* of the language, there is a semantic game G(*S*) between two players, the defender of *S* and the attacker. *S* is true when the defender has a way of winning the game, no matter what the attacker does - that is, when the defender has a winning strategy in G(*S*). *S* is false when the attacker has a winning strategy. The defending player defends a disjunction by selecting a disjunct to defend, since the truth of a disjunction requires only a single disjunct to be true. Since the truth of a conjunction requires both its conjuncts to be true, the attacker attacks a conjunction by selecting a conjunct for the defender to defend. This means that the defender must be able to defend both conjuncts, if the conjunction is to be true. To defend a negation $-S$, it suffices to show *S* false, so the defender of $-S$ is the attacker of *S*, and vice-versa.

A play of G(*S*) eventually comes down to a single atomic sentence *A*. Since the truth-values of nonatomic sentences depend on those of atomic ones, G(*S*) is played against the background of a specified assignment of truth-values to the language's atoms. If *A* is true according to the given assignment, the defender of *A* wins this play of G(*S*), but if it is false, the attacker wins. Truth of *A* is not necessary in order for the initial sentence *S* to be true; for instance, the defender may defend a disjunction unwisely by picking a false disjunct, even if the disjunction is true. *S* is true when the defender of *S* has a winning strategy, which means that there is a way to force any play of G(*S*) to end in victory for that player.

To show an existential quantification to be true, it suffices to find a single true instance. To show a universal quantification false, it suffices to find a single false instance. Thus the defender of an existential sentence selects an individual as an instance of the existential claim, and the attacker of a universal selects an instance of that universal. Again, the universal is true only if the defender can defend every instance that the attacker might select.

When applied to an ordinary first-order language (with no restrictions imposed on strategies available to the players), the assignment of truth-values to sentences produced by game-theoretic semantics (GTS) - on the basis of an assignment of values to the atoms - coincides with the results of the more familiar semantic frameworks. The usefulness of GTS appears when attention turns to natural language, and also when restrictions are imposed on available strategies in games for formal languages.

Unlike most formal languages, English is structurally ambiguous in ways that a semantics must treat (see Ambiguity). For instance, 'Everyone loves someone' is ambiguous between two readings, $(\forall x)(\exists y)(x \text{ loves } y)$ and $(\exists y)(\forall x)(x \text{ loves } y)$, with the former reading strongly preferred. This ambiguity arises in GTS because there are distinct games for the sentence. In one game, the universal quantifier 'everyone' is processed first, thus receiving a wide-scope interpretation so that the first reading is produced. In the second, the existential quantifier 'someone' is processed first. The first reading is preferred because 'everyone' commands 'someone' in the sentence. ('Command' refers to the structural relation of the two quantifiers: the first is 'higher' in the sentence than the second). Thus GTS for English involves a principle that commanding operators must be processed first. This is an 'ordering principle' which governs the structures of semantic games so as to produce preferred readings of ambiguous sentences. Some ordering principles can be absolute, others (like the example above) can be defeasible. Another defeasible ordering principle is that operators should be processed following the left-to-right order of their occurrence in the sentence in question. This principle also applies to 'Everyone loves someone'.

Unlike many approaches to the semantics of English, GTS is not compositional. The interpretation of a sentence need not be determined in a 'cumulative' way based on the predetermined meanings of its components. This

allows GTS to treat various semantic phenomena that do not respond to compositional semantic analysis (see Compositionality).

GTS applied to English yields interesting and novel treatments of such well-known semantic problems as anaphora (determining the conditions for co-reference of pronouns and related singular terms and quantifiers), conditionals, intentional identity, negation and nonstandard informational relationships among operators in a sentence. This can be seen in so-called 'branching quantifiers' and in the interpretation of relational questions. For example, the branching sentence:

$$\left.\begin{array}{l}\forall x \exists y \\ \\ \forall z \exists w\end{array}\right\rangle Fxyzw$$

has *y* within the scope of *x* and *w* within the scope of *z*, but *y* is not within the scope of *z*, nor *w* within the scope of *x*. This pattern of quantifier relationships cannot be represented in a linear first-order quantifier prefix. The semantic game for this sentence is like the game for $\forall x \exists y \forall z \exists w Fxyzw$, except that the game for the branching sentence is a game of imperfect information. The defender of the sentence is ignorant of certain previous moves in the game, whereas the defender of the linear sentence knows what has transpired in the game for that sentence (see Quantifiers §2).

Branching quantification is a well-understood example of informational independence of operators. Informational independence is currently the object of intense study in GTS, which has led to the formulation of 'independence-friendly' logics and the discovery of conditions governing informational variability. Other areas currently of great interest include negation in English and the role of subgames in interpretation. The subgame of a semantic game is a self-contained game serving as a component of the larger game, so that the larger game involves results of the subgame in its play. For example, interpretation of a conditional requires information concerning the semantic game for its antecedent, in order to interpret pronominal connections between the antecedent and consequent. Recent developments have generalized the subgame idea, using 'tangent games' to provide a semantics of relative clauses and to link them to homophonic embedded questions.

Semantics, informational

Information-theoretic semantics (ITS) attempts to provide a naturalistic account of the conditions under which a psychological state such as a belief or desire has a particular mental content: what it is by virtue of which, say, a psychological state is a belief 'that it is raining' or a desire 'that it stop raining'. Because of the complexities of an entirely general account, ITS typically attempts to provide merely a sufficient *naturalistic condition for a belief content of the sort normally acquired by perception (for example, that it is raining). It is expected that other sorts of mental contents may require that ITS be supplemented in various ways.*

ITS was inspired by Claude Shannon's theory of 'information' (1948), which provided a mathematical measure of the amount of information carried by a signal. Employing a notion of 'natural meaning' discussed by Peirce (1931) and Grice (1957), Dretske (1981) supplemented Shannon's work with an account of what *information a signal carries. The intuitive idea is that a signal carries the information 'that* p*' if and only if it naturally means (that is, indicates) that* p*, as when smoke 'means' there is fire.*

Natural indication is a key ingredient in ITS accounts of mental content. In their accounts, Stampe (1977) and Stalnaker (1984) appeal to the notion of what a state indicates under 'optimal' conditions. Fodor (1987) appeals to 'asymmetric dependencies' between the meaning-forming and the non-meaning-forming indication conditions in the causation of psychological states. Dretske (1988) appeals to the idea that, via operant conditioning, a state can acquire a functional role vis-à-vis *behaviour because it naturally indicates 'that* p*' and thereby can acquire the natural function of indicating 'that* p*'.*

1 Content and indication

In an early proposal, Dretske (1981) maintained that a state, *S*, carries the information 'that *p*' (that is, has the informational content 'that *p*') if and only if the probability of *S*, given *p*, is equal to 1 (see Information theory). One issue this proposal raises is whether the probability is 'objective' or 'subjective' (a matter of degrees of belief) (see Probability, interpretations of). If the notion of information content is to be suitable for a naturalistic account of mental content, the notion of probability invoked must be objective. But, as Dretske himself pointed out, the relevant notion of probability is not relative frequency. Moreover, it seems not to be propensity either: the direction of propensity is the direction of causation; but the conditional probability Dretske would have us consider is the opposite direction: the probability of there being 'fire', given that there is 'smoke'. In a later proposal, Dretske (1988) employed a counterfactual: the occurrence of a state, *S*, carries the information that *p* if and only if *S* would not have occurred unless *p*. He claimed that such counterfactuals express objective, mind-independent facts.

2 Two problems

Error. A state carries the information 'that *p*' if and only if it indicates (or naturally means) 'that *p*'. But a state indicates 'that *p*' only if *p* is indeed the case. So information, in the sense of natural indication, does not admit of misinformation, or error. However, belief does: one can believe 'that *p*' even when *p* is false. How can information-theoretic semantics (ITS) accommodate this fact?

Fine-grained individuation. Moreover, even when a belief 'that *p*' indicates 'that *p*', the indication relation will not uniquely pair the belief with *p*. The belief 'that *p*' can differ from the belief 'that *q*', even when *p* and *q* are logically equivalent. For example, the belief that 'there is a chair in the room' has a different content from the belief that 'there is a chair in the room and it is either an antique or not an antique', even though these contents are logically equivalent. However, if a state indicates *p*, then it indicates anything that is logically equivalent to *p*. Indeed, if a state indicates 'that *p*', then it indicates anything that is merely nomologically equivalent to *p*: for example, anything that indicates the presence of a renate (creature with kidneys) indicates the presence of a cordate (creature with a heart). Moreover, if something indicates 'that *p*', then it indicates anything that logically or even nomologically follows from *p*: anything that indicates that something is a cow indicates that it is a herbivore. Yet the belief that something is a renate is different from the belief that it is a cordate, a belief that something is a cow is different from the belief that it is a herbivore.

3 Three proposals

Optimal conditions. Stampe (1977), Fodor (1990b) and Stalnaker (1984) try to accommodate the possibility of error or misrepresentation by maintaining that the content of a psychological state is what the state would indicate under 'optimal' conditions. Stalnaker's proposal is that a belief state has the content 'that *p*' if and only if, in optimal conditions, the state indicates *p,* and the subject is in the state because *p* or because of something that entails *p*. The idea is that in cases of false belief, conditions are not optimal (see Idealizations).

One problem is that it is by no means clear that the notion of ideal conditions is suitably naturalistic. Belief fixation is holistic: what someone would come to believe in some situation depends on what they already believe about other things. Even in a good light, someone presented with a horse might not think it is one if they think appearances are misleading. If optimal conditions must include the subject's being in belief states with certain contents, then, as an account of belief content, ITS is circular.

Asymmetric dependencies. Fodor (1987) formulates his ITS theory as one for mental symbols - expressions in a 'language of thought' (see Language of thought). He calls tokens of mental symbols meaning 'cow' that are caused in the absence of cows 'wild', and calls the property whereby symbols can mean things that on occasion are not causes of their tokening 'robustness'. He points out that in solving problems of robustness and error, ITS needs to solve the 'disjunction' problem: given that among the causes of a symbol's tokenings, there are both meaning-forming and wild causes, what distinguishes them? In particular, what makes it true that some symbol *F* means [horse] and not [horse or cow on a dark night] or [horse or cow on a dark night or w_2 or w_3 or…] (where each w_i is a property the exemplification of which could cause the tokening of *F*)?

Fodor speculates that a state's being caused by wild conditions depends upon its being caused by meaning-constitutive ones, but not vice versa: ill-lit cows causing horse thoughts depends upon well-lit horses causing them, but well-lit horses causing them does not similarly depend upon the ill-lit cows doing so (getting things wrong depends upon getting things right in a way that getting things right does not depend upon getting things wrong). Fodor draws from this speculation the proposal that mention of ideal conditions is inessential: the structure of this asymmetric causal dependency alone, abstracted from any specific conditions or causal chains, can do all the work.

One problem with this suggestion is that there are many asymmetric dependencies even within meaning-forming cases: for example, small horses causing horse thoughts might asymmetrically depend upon all horses doing so, but not vice versa. If this were so, Fodor would be committed to claiming that 'horse' meant 'non-small horse'.

Another problem is that, in avoiding any mention of mentality, the account risks gratuitous meanings that are brought about by the physics of the world but have no cognitive significance for the agent: electrical stimulation by a poking neurosurgeon, or by cosmic rays, causing tokenings of a mental state in one set of circumstances (for example, when potassium levels were high), might depend upon their lawfully causing those tokenings under other circumstances (when sodium levels were low, for example), but not vice versa. Fodor's view would seem to be committed to treating these further phenomena as meanings, albeit of no cognitive relevance to the agent.

Fodor (1987, 1990a) has replied to these objections with considerable ingenuity. However, what is needed is not only to rule out cases one-by-one, but some general reason to believe that the relevant notion of asymmetric dependency can be explicated without appeal to any mentalistic notions.

Indicator functions. Dretske's most developed ITS proposal is that a mental state has the content 'that *p*' if and only if it is has the *function* of indicating *p*. This distinguishes a proper subset of natural indications; moreover, errors arise when the state fails to indicate what it has the function of indicating. The problem of consequences is handled by observing that from the fact that a state has the function of indicating 'that *p*', and *p* implies *q*, it does not follow that the state has the function of indicating that *q* (see Semantics, teleological; Functional explanation).

The main burden of this approach is to say what makes it the case that a state has a certain indicator function. Dretske offers an account of how a state can acquire such a function, and uses it to offer an account of what he calls 'proto-beliefs' and 'proto-desires'. Suppose that a state *B* of an organism indicates that some property or kind *F* (for example, water) is present in the organism's vicinity, and that a state *D* of the organism renders it receptive to a reward *R*. Then, when in *D*, the organism's behaviour can be reinforced by *R*. Suppose further that when *B* and

D jointly contribute to producing a movement *M* in circumstances in which *F* is present, this results in the organism's receiving *R*. Then, through a process of operant conditioning, *B* and *D* can come to have the 'control' duty of producing *M*. State *B* can thus acquire the control duty because it indicates *F*, and *D* can thus acquire this duty because it is a state of receptivity for *R*. According to Dretske, if *B* and *D* were recruited in this way for the control duty of producing some movement, *B* has the natural function of indicating that *F* is present, and *D* counts as a proto-desire for *R*.

A problem for this account is whether it can be naturalistically supplemented to yield an account of beliefs and desires themselves, since pairs of beliefs and desires do not generally have a specific control duty *vis-à-vis* movements: desiring water and believing there is some in the brook, does not necessarily give rise to any specific behaviour. And, of course, this account is inapplicable for beliefs and desires not acquired by operant conditioning (see Behaviourism, analytic; Behaviourism, methodological and scientific).

Moreover, appeals to function arguably fail to solve the problem of fine-grained individuation. If *p* and *q* are logically equivalent or even nomologically equivalent, then the mechanisms of operant conditioning will be insensitive to their difference (see Intentionality; Propositional attitude statements). Consequently, a state will have the natural function of indicating 'that *p*' if and only if it has the natural function of indicating 'that *q*'. Indeed, whenever *p* and *q* are such that the mechanisms of operant conditioning are insensitive to their difference, whatever has the natural function of indicating *p* has the natural function of indicating *q*. Thus, if, for instance, such mechanisms are insensitive to the difference between the presence of a 'rabbit' and the presence of 'undetached rabbit parts' (to borrow a famous example from Quine 1960), it seems that a state will have the function of indicating that a rabbit is present if and only if it has the function of indicating that undetached rabbit parts are present.

4 Two-factor theories

Since Brentano, it has seemed to many philosophers undeniable that the mind makes more distinctions than even all possible worlds provide: the mind can conceive the impossible, and distinguish among even necessarily co-instantiated properties (like 'being an equiangular triangle' and 'being an equilateral triangle'). 'Two-factor' theories claim that there is something about a mental state in addition to what is captured by ITS that supplies the additional distinctions, notably, its structure or its conceptual role. Fodor (1990a), doubting that conceptual roles can be specified in a way immune to Quine's criticisms of the analytic/synthetic distinction, holds that what distinctions are needed can be captured by structures specified in a language of thought. Others (Block 1986, for example) think that once conceptual roles are specified purely internally, independently of issues of truth, Quine's criticisms are no longer a worry. Most defenders of ITS agree that capturing the contents of logically complex, non-perceptual beliefs (for example, that 'not every particle retains charge if divided') requires reference to some internal factor (see Semantics, conceptual role §3; Concepts §10).

Semantics, possible worlds

Possible worlds semantics (PWS) is a family of ideas and methods that have been used to analyse concepts of philosophical interest. PWS was originally focused on the important concepts of necessity and possibility. Consider:

(a) Necessarily, $2+2=4$.
(b) Necessarily, Socrates had a snub nose.

Intuitively, (a) is true but (b) is false. There is simply no way that 2 and 2 can add up to anything but 4, so (a) is true. But although Socrates did in fact have a snub nose, it was not necessary that he did; he might have had a nose of some other shape. So (b) is false.

Sentences (a) and (b) exhibit a characteristic known as intensionality*: sentences with the same truth-value are constituent parts of otherwise similar sentences, which nevertheless have different truth-values.* Extensional semantics *assumed that sentences stand for their truth-values, and that what a sentence stands for is a function of what its constituent parts stand for and how they are arranged. Given these assumptions, it is not easy to explain the difference in truth-value between (a) and (b), and hence not easy to give an account of necessity.*

PWS takes a sentence to stand for a function from worlds to truth-values. For each world, the function yields the truth-value the sentence would have if that world were actual. '$2+2=4$*' stands for a function that yields the truth-value 'true' for every world, while 'Socrates had a snub nose' stands for a different function that yields 'true' for some worlds and 'false' for others, depending on what Socrates' nose is like in the world. Since these two sentences stand for different things, sentences that have them as constituents, such as (a) and (b), can also stand for different things.*

This basic idea, borrowed from Leibniz and brought into modern logic by Carnap, Kripke and others, has proven extremely fertile. It has been applied to a number of intensional phenomena in addition to necessity and possibility, including conditionals, tense and temporal adverbs, obligation and reports of informational and cognitive content. PWS spurred the development of philosophical logic and led to new applications of logic in computer science and artificial intelligence. It revolutionized the study of the semantics of natural languages. PWS has inspired analyses of many concepts of philosophical importance, and the concept of a possible world has been at the heart of important philosophical systems.

1 Intensions demeaned

Traditionally, the 'intension' of a predicate was distinguished from its 'extension'; the former is a property, the latter is a set. The predicates 'is a featherless biped that is not a plucked chicken' and 'is human' have (one can imagine) the same extensions but different intensions. (The example is from Bertrand Russell.) Gottlob Frege's concepts of *Sinn* and *Bedeutung* extend this idea: the *Sinn* of a singular term is an identifying condition (or 'individual concept'), the *Bedeutung* the individual designated. The *Sinn* of a sentence is a proposition, the *Bedeutung* a truth-value. Frege defended his choice of truth-values as the *Bedeutung* of sentences on systematic grounds (see Frege, G.; Sense and reference).

As model theory was developed by Tarski and others, a version of Frege's choices for *Bedeutung* became the standard values in 'extensional semantics'. The extension of an *n*-place predicate is the set of *n*-tuples of objects of which the predicate is true (thus, the extension of 'gives' might be the set of those four-tuples containing two persons, an object and a time, such that the first person gives the object to the second person at that time). The extension of a singular (object-denoting) term is the object it designates. The extension of a sentence is a truth-value (see Model theory). The packaging together of the predicate calculus with an extensional semantics proved adequate for important work in mathematical logic and overshadowed older approaches to logic. In contrast, no understanding of intensions emerged that is generally agreed on. In the middle part of the century interest in intensional phenomena waned. In fact, the success of extensional logic led to somewhat uncharitable attitudes towards any non-extensional phenomena. In Quine's influential view non-extensional constructions are not suited for scientific work; they are more in need of regimentation than straightforward analysis (see Quine, W.V.). (Non-extensional constructions are those that apparently distinguish between different phrases or sentences

used to complete them, even though the phrases or sentences have the same extensions. One example is 'Elwood believes that…'. 'Elwood believes that Stanford is east of Hawaii' might be true, while 'Elwood believes that Stanford is east of Berkeley' might be false, even though 'Stanford is east of Hawaii' and 'Stanford is east of Berkeley' both have the same extension (the truth-value 'true'). 'Intensional' is sometimes used simply to mean 'non-extensional', and is sometimes given a narrower meaning.)

2 Modal logic

A number of philosophers and logicians continued to attempt to provide straightforward analyses of intensional phenomena, however. Until the 1950s, the emphasis was on syntactic approaches. A key figure was C.I. Lewis, whose dissatisfaction with the extensional treatment of 'if…, then…' as the material conditional led him first to the logic of 'strict implication', then to 'modal logic', the logic of necessity and possibility (see Lewis and Langford 1932). The modal operators (typically translated 'necessarily' and 'possibly', and usually symbolized as $\Box$ and $\Diamond$) are not truth-functional, and so require intensional analysis.

The language of propositional modal logic (ML) consists of the language of propositional logic, plus the rule that if ϕ is a well-formed formula (wff), then so are $\Box\phi$ and $\Diamond\phi$. Lewis and others worked out a number of axiom systems for ML and studied and compared them proof-theoretically.

More semantically oriented approaches to intensionality emerged later in the century, beginning with Carnap (1946, 1947). One of the most important of Carnap's many contributions to the study of intensionality was to recruit Leibniz's idea that necessary truth was truth 'in all possible worlds' to the task of building an intensional semantics. This is the guiding idea of possible worlds semantics (PWS). Carnap's version of this idea, less straightforward than those that were to follow, relies on linguistic representations of possible worlds which he called 'state-descriptions'.

The basics of the now-standard treatment came in the late 1950s and early 1960s with results obtained by Stig Kanger (1957; also Føllesdal 1994) and Saul Kripke (1959, 1963a, 1963b; also Hintikka 1957, Montague 1974a). We shall look briefly at K, S4 and S5, three among the plethora of axiom systems for modal logic that have been studied.

S5 includes:

- all propositional tautologies and *modus ponens*,
- the definition $\Diamond\phi =_{\mathrm{df}} \neg\Box\neg\phi$,
- the rule of necessitation ($\vdash\phi \;/\; \vdash\Box\phi$, that is, if ϕ is deducible from the null set of premises, then so is $\Box\phi$),
- the axioms

[*K*]: $\Box(\phi\rightarrow\psi)\rightarrow(\Box\phi\rightarrow\Box\psi)$
[*T*]: $\Box\phi\rightarrow\phi$
[*4*]: $\Box\phi\rightarrow\Box\Box\phi$
[*B*]: $\Diamond\Box\phi\rightarrow\phi$

If we drop B we have S4; if in addition we drop *4* and *T* we have $\mathbf{K}$, Kripke's minimal system.

A modal model structure is a pair $\langle K,R\rangle$. *K* is the set of worlds; *R* we will consider later. A modal model will tell us which atomic sentences of the base language *L* are true at which worlds of *K*. For the connectives of propositional logic the rules remain unchanged. To extend the system to include $\Box$ it is natural, on the Leibnizian conception, to use the rule (we symbolize 'ϕ is true in *w*' as $\phi[w]$):

$\Box_A$: $\Box\phi[w]$ iff $\forall w'\phi[w']$.

Given the definition of $\Diamond$ we have:

$\Diamond\phi[w]$ iff $\exists w'\phi[w']$.

The reader can check that on this conception, all of the axioms for S5 are valid, that is, true in every world of every model. Consider *B*, for example. Suppose the antecedent is true at *w*. Then $\exists w'\forall w''\phi[w'']$. Since the existential

quantification is vacuous, this reduces to $\forall w' \phi[w']$. Then, by Universal Instantiation (U.I.), we have $\phi[w]$.

Note that the $\Diamond$ was vacuous; $\Diamond\Box\phi$ collapsed into $\Box\phi$. This is characteristic of S5: iterated modalities collapse to the right.

S5 is a natural logic for metaphysical necessity, which was doubtless the conception Leibniz had in mind. But there are other coherent concepts of necessity, for which some of the axioms of S5 do not seem correct, and for which distinctions among iterated modalities are significant (see Modal logic).

Consider physical necessity. We have $\Box\phi[w]$ if ϕ is true in every world that obeys the laws of physics of *w*. Suppose w' is a world which has all of our laws and more. Certain events may be ruled out by the physics of w' that are not ruled out by our physics, so our world is not physically possible relative to w'. Suppose, for example, that it is a law of physics in w' that no golf ball travels more than 200 yards. Then even though w' is physically possible (it obeys our laws) and 'No golf ball travels over 200 yards' is necessary in w', it is not true that no golf ball travels over 200 yards. So Axiom *B* is incorrect for physical necessity.

T is intuitive in the case of metaphysical and physical necessity, but not for 'deontic logic', in which '$\Box\phi$' is interpreted as 'It ought to be the case that ϕ' (see Deontic logic).

In discussing these alternative conceptions of necessity and possibility, we move from an absolute to a relative conception of possibility, the idea that the set of worlds relevant to issues of necessity varies from world to world. This is the information given by the second member of the model structure above. *R* is a relation on *K*, the 'accessibility relation'. Different accessibility relations correspond to different conceptions of necessity. We replace our absolute rule $\Box_A$ with a relative rule:

$\Box_R$: $\Box\phi[w]$ iff $\forall w'$, if w' is accessible from w, then $\phi[w']$.

The axioms that characterize the various systems of modal logic correspond to the logical properties of the relation *R*. The axiom *K* places no restrictions on it; *T* requires reflexivity; *4* requires transitivity; and *B* symmetry. Thus absolute necessity, captured by S5, is the case where the accessibility relation is an equivalence relation.

3 Other applications

The semantical apparatus developed for modal logic has been used to investigate a number of other logical systems.

In 'epistemic logic', for example, a knowledge operator, indexed by knowers, is patterned after $\Box$; $K_\alpha\phi$ means 'ϕ holds in all of α's epistemic alternatives' (Hintikka 1962; see Epistemic logic).

It is important for the philosophically oriented reader to keep in mind that for the purposes of developing and applying semantical treatments of intensional languages, for example, in completeness proofs, the possible worlds of PWS need not be invested with any important metaphysical properties; they are just indices for models. The basic apparatus has been used to study a number of areas in which the metaphor of a possible world is inapplicable. In dynamic logic, for example, the apparatus of modal logic is applied to programs. The 'worlds' are states of a machine. Accessibility relations are indexed by programs. Where α is a program, $\Box[[\alpha]]\phi$ means 'ϕ holds after every terminating execution of α' (see Pratt 1976; Dynamic logics).

The interplay between semantic structures and logical systems involved in these investigations constitute a development in logic comparable to the move in geometry away from Euclidean geometry, conceived as the one true system, to geometry as the study of alternative axiom systems for spaces with diverse properties.

4 Temporal logic

The apparatus of modal model structures works nicely to provide a semantics for temporal logic - the logic of operators modelled after the tense and temporal adverb systems of natural languages. Let '*G* mean 'It will always be the case' and '*F* mean 'It will sometimes be the case'; '*F* can be defined as '$\neg G \neg$'. Thus *G* is a universal operator, analogous to $\Box$, and *F* is an existential operator, analogous to $\Diamond$. Similarly, let '*H* mean 'It has always been the case' and define '*P*' as '$\neg H \neg$'. Then instead of a set of worlds and an accessibility relation, take a model structure to be a set of moments of time and an ordering relation between them. The need for an accessibility

relation is rather more intuitive here than in the case of necessity and possibility since, unlike worlds, we usually think of times as ordered by the relation of ‘before’. As with modal logic, different logics correspond to different conceptions of the ordering relation. One minimal tense logic (Benthem 1988) contains the axioms:

- $G(\phi \rightarrow \psi) \rightarrow (G\phi \rightarrow G\psi)$
- $H(\phi \rightarrow \psi) \rightarrow (H\phi \rightarrow H\psi)$
- $\phi \rightarrow GP\phi$
- $\phi \rightarrow HF\phi$

and the rules *modus ponens* and the analogue to necessitation, sometimes called ‘eternity’:

- $\vdash \phi / \vdash G\phi$
- $\vdash \phi / \vdash H\phi$

As with modal logic, there is a precise correspondence between ordering conditions and additional axioms. For example $PP\phi \leftrightarrow P\phi$, which seems plausible enough, requires that the structure of moments be transitive (if *t* is before t' and t' is before t'', *t* is before t'') and dense (if *t* is before t', there is a t'' between them, that is, after *t* and before t') (see Prior 1967; Benthem 1988; Tense and temporal logic).

5 Conditional logic

As we noted, dissatisfaction with the material conditional as an explication of the ordinary-language conditional was an early complaint against extensional logic. There is some connection between the antecedent and the consequent that the semantics for the material conditional misses. For one thing, $\phi \rightarrow \psi$ is true whenever ϕ is false, making all counterfactual conditionals trivially true. Let us use ‘ $\Rightarrow$’ as a symbol for a better approximation. Another key way in which $\Rightarrow$ should differ from $\rightarrow$ is that it should not always permit *strengthening the antecedent*. We have:

$(\phi \rightarrow \psi)$ only if $(\phi \wedge \chi \rightarrow \psi)$

but not:

$(\phi \Rightarrow \psi)$ only if $(\phi \wedge \chi \Rightarrow \psi)$.

For example:

ϕ: I put water in my canteen when I start my hike.
ψ: I have water when I stop for a rest.
χ: There is a hole in my canteen.

Robert Stalnaker’s version of Frank Ramsey’s test for evaluating conditionals is ‘make the minimal revision of your stock of beliefs required to assume the antecedent. Then, evaluate the acceptability of the consequent on the basis of this revised body of beliefs’ (Ramsey 1931). Stalnaker (1968) and David Lewis (1973) have proposed analyses that implement this idea within the possible worlds framework:

Stalnaker: $\phi \Rightarrow \psi[w]$ iff ψ holds in the ϕ-world that is closest to *w*.
Lewis: $\phi \Rightarrow \psi[w]$ iff ψ holds in *all* ϕ-worlds which are closest to *w*.

These analyses require a relation of overall similarity or closeness among worlds. (It can be argued that the relation of overall similarity of worlds is vague and context sensitive; it is replied that this captures the vagueness and context sensitivity of the ordinary conditional.)

On either analysis, strengthening the antecedent fails for $\Rightarrow$, because when the antecedent is strengthened, different worlds might be the closest in which the antecedent is true.

The choice between Lewis’ definition and Stalnaker’s depends on such issues as whether there is always a unique closest world. One important principle that turns on this is ‘conditional excluded middle’,

$(\phi \Rightarrow \psi) \vee (\phi \Rightarrow \neg\psi)$

which Stalnaker endorses and Lewis rejects (see Indicative conditionals; Counterfactual conditionals).

6 Quantified modal logic

In 1946, Ruth Barcan Marcus and Rudolf Carnap independently published systems of quantified modal logic (QML), in which principles like the following were considered:

$$\forall x \Box \phi(x) \rightarrow \Box \forall x \phi(x)$$

This is the ‘Barcan formula’, attractive to those who would reduce *de re* to *de dicto* necessity (see De re/de dicto).

Kripke (1963b) has provided a semantics for these systems. A quantificational modal structure $\langle K, R, \Psi \rangle$ adds a function Ψ which assigns a domain of individuals to each possible world in *K*. A model assigns extensions to each predicate at each world. On the natural, ‘world-bound’ interpretation of universal quantification, $\forall x \phi(x)$ is true in a world *w* if and only if in *w* $\phi(x)$ is true of every member of the domain of *w*.

If we suppose, as is natural, that worlds have varying domains (that objects that might have been in our world, for example, actually exist in other worlds), then it seems the Barcan formula is not valid. Even if every object we find in the actual world is ϕ in all possible worlds, there could be objects in other possible worlds that are not ϕ. But the formula can be validated if we interpret quantifiers as ranging over all possible objects, or if we suppose that the domain is constant across worlds; each of these alternatives have found proponents.

‘Quantifying in’ (that is, quantification across modal operators as in the antecedent of the Barcan formula) was deemed by Quine to put us in danger of a commitment to ‘essentialism’. Suppose Quine is in the extension of ‘is a Kantian’ in some possible world *w*. This fact about the realm of possibility is not a fact about the necessary or possible truth of some sentence, so there is some commitment to *de re* modality. Note however that accepting such facts as these does not commit one to a view that Quine must have an essence that distinguishes him from all other objects, one natural understanding of ‘essentialism’ (Føllesdal 1986) (see Modal logic, philosophical issues in §3).

7 Index theory and intensional logic

Starting in the late 1960s, PWS began to find a role beyond providing semantics for particular logical systems. One development was the development of ‘intensional logics’ that combined modal, temporal and other operators (see Intensional logics).

We can think of time and possible worlds, for example, as two dimensions along which the truth of a sentence can vary; from this point of view, it is natural to provide a semantics for a system in which sentences are true in worlds at times, and that contains both temporal and modal operators. Thus, for example,

$$\Box(H\phi)$$

will be true in world *w* at time *t* if and only if in every world w' accessible to *w*, at every time t' earlier than *t*, ϕ is true at w' and t'.

But there are also other factors relative to which the truth of sentences can vary. In particular, sentences containing indexicals (such as ‘I’, ‘you’, ‘here’ and ‘now’) will vary in truth depending on who says them, to whom, where and when.

Thus we could think of:

I will walk to the shop

as being true at a world *w*, time *t* and person *a*, if in *w*, *a* walks to the shop at some time subsequent to *t*.

Following the advice of Dana Scott, Montague, Lewis and others developed and explored versions of ‘index theory’, systems in which sentences were true at an index, where indices were *n*-tuples of worlds, times, speakers and other factors (see Scott 1970; Montague 1974b; Lewis 1970).

Kamp’s ‘double-indexing’ (1971), Segerberg’s ‘two-dimensional modal logic’ (1973) and Kaplan’s ‘logic of demonstratives’ (1989) provide alternatives to index theory. These authors emphasize the difference between *reliable* sentences such as ‘I am here now’, that, even if they express contingent propositions, cannot be uttered

falsely, and sentences such as ‘either there are cats or there are not’, that are valid in the standard sense, of being true in every world in every modal model.

8 Montague semantics

Richard Montague was a leader in the development of intensional logic. In his early papers, he developed PWS as a tool for investigating a number of phenomena of philosophical interest, such as sense-data and events. In later work he developed PWS as a powerful tool for model-theoretic treatments of the semantics of English and other natural languages. Montague’s work has had a profound influence in linguistics (see Partee 1989).

As the body of Montague’s work developed, intensional phenomena were increasingly seen not as exceptional and marginal, but as at the core of the way language works. In modal logic, intensionality derives from special operators added onto a base language that works on extensional principles. In Montague semantics, intensionality is a ubiquitous phenomenon; there are not only intensional operators, but intensional verbs, adjectives, adverbs and so on. In Montague’s later work, intensionality is basically the default case, with special postulates to guarantee extensionality (1974c).

By using intensional logic and PWS to give a precise semantics for constructions of natural language, Montague developed an important new subdiscipline of linguistics, often simply called ‘Montague Grammar’.

9 Intensions triumphant

PWS provides philosophy with a toolkit of entities for the analysis of intensional phenomena:

- For individual concepts: functions from worlds to individuals.
- For properties: functions from worlds to extensions.
- For propositions: functions from worlds to truth-values (or sets of worlds).

Note that these functions are themselves extensionally understood, and so analysable within the framework of set theory, and (in that sense at least) free of obscurity.

By the 1970s, philosophers were availing themselves of these tools to talk in disciplined ways about many traditional and some new issues, issues often not directly connected with the interpretation of systems of logic. A few of these are:

- Quantified modal logic has been at the heart of a productive rethinking of issues involved in the distinction between *de dicto* and *de re* necessity, beginning with Quine’s charge that quantified modal logic commits us to essentialism (see Føllesdal 1986; Essentialism).
- PWS provides two models for the semantics of names. On the possible worlds version of the Frege-Russell-Searle descriptive account of names, the meaning of a name is an individual concept. An alternative is to model names on variables directly assigned to individuals, the same for all worlds, irrespective of their properties in the worlds. Marcus (1961) suggested the latter possibility, and in *Naming and Necessity* (1980), Saul Kripke has mounted a full-scale challenge to the descriptive account, arguing that names are ‘rigid designators’ (referring to the same object in all worlds), and providing a causal account of the link between name and thing as an alternative to the descriptive account (see Proper names).
- David Kaplan, whose lectures, seminars and unpublished writings stirred much interest in PWS throughout the 1970s, worked out an account of indexicals and demonstratives in the context of index theory. This has led to a clarification of a number of issues involving the semantics and epistemology of indexicals (see Kaplan 1989; Demonstratives and indexicals).
- David Lewis has used the apparatus of PWS to make significant contributions to our understanding of convention, the semantics of natural language, the understanding of counterfactuals (see above) and many other issues in metaphysics, epistemology and the philosophy of science (see Lewis 1970, 1973, 1979).

Lewis’ own view of possible worlds maintains that possible worlds are alternative concrete realities; they are actual for their inhabitants, as ours is for us. The inhabitants of other worlds are not identical with the inhabitants of the actual world (that is, our world), but are their *counterparts*; Lewis’ account of quantification is based on the counterpart relations rather than identity.

10 All the intensions we need?

Can PWS supply philosophy with all the intensions that are needed to understand intensional phenomena? Can all intensions be understood as functions from worlds to appropriate sets?

One of the most difficult challenges is the problem of propositional attitudes. The basic problem is that PWS supplies only one necessary proposition (the set of all worlds) and only one contradictory proposition (the null set). This seems to pose a severe problem for dealing with mathematical knowledge. Given usual principles of compositionality, we could infer from 'Elwood knows that $7+5=12$' to 'Elwood knows that *S*' for any true mathematical sentence *S* or any other necessary truth for that matter.

Robert Stalnaker (1984) has given an careful and extended defence of the use of PWS in epistemology. He argues that the concept of content needed for propositional attitudes is grounded in pragmatic relations and such informational relations as indication. The problem of mathematical knowledge, he argues, can be resolved by seeing a linguistic element in our knowledge of mathematical truths.

Advocates of situation semantics have argued, however, that the possible worlds analysis of indication is also vitiated by the problem of the single necessary proposition. Where *P* is a contingent proposition and *N* is the necessary proposition, $P = P \,\&\, N$. So if the tree rings indicate that the tree is one hundred years old, they also indicate that it is one hundred years old and $7+5=12$. But indication appears to distribute over conjunction, so we could infer that the tree rings indicate that $7+5=12$ (see Perry 1993; Semantics, situation).

While these and other problems have stimulated great interest in other approaches to intensionality in recent years, it seems fair to say that PWS has had by far the most impact on the disciplined investigation of intensional phenomena and that no alternative treatment yet devised provides as natural and comfortable a scheme for thinking about intensional matters.

Semantics, situation

Situation semantics attempts to provide systematic and philosophically coherent accounts of the meanings of various constructions that philosophers and linguists find important. It is based on the old idea that sentences stand for facts or something like them. As such, it provides an alternative to extensional semantics, which takes sentences to stand for truth-values, and to possible worlds semantics, which takes them to stand for sets of possible worlds.

Situations are limited parts or aspects of reality, while states of affairs (or infons) are complexes of properties and objects of the sort suitable to constitute a fact. Consider the issue of whether Jackie, a dog, broke her leg at a certain time T. There are two states of affairs or possibilities, that she did or she did not. The situation at T, in the place where Jackie was then, determines which of these states of affairs (infons) is factual *(or* is the case *or* is supported*).* Situation theory*, the formal theory that underlies situation semantics, focuses on the nature of the* supports *relation.*

Situation semantics sees meaning *as a relation among* types of situations. *The meaning of 'I am sitting next to David', for example, is a relation between types of situations in which someone A utters this sentence referring with the name 'David' to a certain person B, and those in which A is sitting next to B. This relational theory of meaning makes situation semantics well-suited to treat indexicality, tense and other similar phenomena. It has also inspired relational accounts of information and action.*

1 History of situation semantics

Situation semantics was originally conceived as an alternative to extensional model theory and possible world semantics especially suited to the analysis of various problematic constructions, including naked-infinitive perception verbs (Barwise 1981) and belief-reports (Barwise and Perry 1981a) (see Model theory; Semantics, possible worlds). In its earliest forms, the central ideas were:

• *Partiality.* Situations are contrasted with worlds; a world determines the answer to every issue - the truth-value of every proposition. A situation corresponds to the limited parts of reality we in fact perceive, reason about, and live in. What goes on in these situations will determine answers to some issues, but not all. In 'Scenes and Other Situations' (1981), reporting his initial work on situation theory, Jon Barwise represents scenes, the situations we perceive, as partial first-order models.
• *Realism.* Basic properties and relations are taken to be real objects - uniformities across situations and objects - not bits of language, ideas, sets of *n*-tuples, or functions. In *Situations and Attitudes* (Barwise and Perry 1983), 'courses of events' are partial functions from sequences of locations, relations and objects to truth-values. Complex properties and relations, and various types of objects were full-fledged objects, entering into courses of events.
• *The relational theory of meaning.* The meaning of an expression ϕ is conceived as a relation between a discourse situation, a connective situation and a described situation, written:
$_{d,c}[[\phi]]_e$

The meaning of 'I am sitting next to David', for example, would obtain between courses of events *d*, *c* and *e* if there are individuals *a* and *b* such that (1) in *d*, *a* is the speaker of the sentence; (2) in *c*, *a*'s use of 'David' is used to refer to *b*; and (3) in *e*, *a* is sitting next to *b*.

A number of trenchant criticisms were made of *Situations and Attitudes* (see especially Soames 1985). In reaction to them, Barwise and Perry (1985) recognized the need to rethink the foundations of situation semantics. Two main developments bridge the early versions of situation semantics and the later ones which emerged from this rethinking:

(1) In early versions, situation semantics was developed within standard set theory; this led to foundational problems. In the mid-1980s, Barwise and others developed various versions of 'situation theory', in which all of the various entities that had become necessary were treated axiomatically (Barwise 1989; Devlin 1991; Westerståhl 1990) or within Peter Aczel's version of set theory (Barwise and Etchemendy 1987).

(2) The concept of a constraint, developed in *Situations and Attitudes* as an adjunct to the relational theory of meaning, has become central to the development of situation semantics as a general account of informational and intentional content (Barwise 1993; Israel and Perry 1990; Perry 1993).

2 Situations

The basic idea of situation semantics is that in thought and action we use complexes of objects and properties to classify 'directly' and 'indirectly' parts and aspects of reality, or 'situations'. This sort of realistic classification is more basic than linguistic classification, and it underlies linguistic classification. Consider a simple dialogue:

'What happened in the woods this afternoon?'
'Jackie broke her leg.'

The question concerns a certain situation, a bit of reality: the events in the woods this afternoon. The answer directly classifies the situation in terms of an object (the dog Jackie) and a property (acquiring a broken leg). We classify situations by what goes on in them, by which properties objects have, and by the relations they stand in to one another in virtue of the events that comprise the situation.

Consider the issue of whether Jackie broke her leg at a certain time *t*. There are two dual possibilities or 'states of affairs', corresponding to whether her leg was broken or not, which we can represent as:

σ: $\langle\langle \mathrm{breaks\ leg}, t, \mathrm{Jackie}; 1\rangle\rangle$

and

σ': $\langle\langle \mathrm{breaks\ leg}, t, \mathrm{Jackie}; 0\rangle\rangle$

Of course, what goes on in the whole world (if we assume there is such a totality) will determine whether or not Jackie broke her leg, but this will also be determined by much smaller situations. Let *s* be the situation in the woods this afternoon. Then,

$s \models \sigma$

that is, *s supports* σ, or (in more traditional philosophical terms) *s makes it the case* that σ, or *makes* σ *factual*.

In situation theory, various objects are built from the basic interplay of situations and states of affairs, permitting complex and abstract ways of classifying situations, including complex states of affairs, properties and relations. A key concept is a 'type of situation', such as the type of situation in which a dog breaks its leg (call it *S*) and the type of situation in which a dog does not run (call it S').

There are states of affairs involving these abstract objects. In particular, one type of situation may involve another: if there is a situation of the first type, there will also be one of the second type. *S* involves S': dogs with broken legs do not run. These sorts of states of affairs are 'constraints'.

3 Meaning

Constraints give rise to the possibility of 'indirect classification': classifying situations by what they mean. That is, classifying situations not by the states of affairs they support, but by the types of situations they involve, relative to some constraint.

Indirect classification is how situation semantics conceives of informational and intentional content. Classifying situations by their contents is what organisms do under the influence of what Hume calls 'custom': confronted with a situation, they form expectations, or at least contemplate possibilities, on the basis of what the situation involves relative to some constraint, factual or not, to which they have become attuned. Situation semantics interprets informational and intentional content as a system that exploits such indirect classification. Situations are indirectly classified relative not only to laws of nature and other actual constraints (informational content), but also to conventions, rules, customs, plans and other constraints, both factual and fictional, of human contrivance (intentional content).

Consider:

(1) Jackie has a broken leg.
(2) The x-ray shows that Jackie has a broken leg.
(3) The vet said that Jackie had a broken leg.

In (1), we have direct classification; in (2) and (3), indirect classification. In the latter a common pattern is discernible, involving three types of situation and a constraint:

- A local situation.
- Connections between objects in that situation and other objects, the 'subject matter'.
- A remote situation, the content, involving the subject matter.
- A constraint according to which a combination of situations of the first two types involves a situation of the third type.

In (2) the local situation is the x-ray having certain characteristics. The x-ray is connected to Jackie: it was taken of her. The complex type of situation, in which an x-ray taken of a certain dog exhibits those features, involves a situation in which the dog has a broken leg. Given the connections between the x-ray and Jackie, its having those characteristics shows that she has a broken leg. Here the constraint is factual and the content is informational.

In (3) the local situation is the utterance, in which the vet utters the words 'Jackie has a broken leg'. The vet's use of the word 'Jackie' is connected through various mental and conversational links to the dog Jackie. The rules of English provide the constraint: given the characteristics of the utterance and its connections, it is true if and only if Jackie has a broken leg. English speakers are attuned to these constraints, not in the sense that they automatically form expectations when they hear utterances, but in the sense that they grasp the type of situation meant. Here the content is intentional.

Situation semantics then conceives of meaning as a relation between types of situations. A key advantage of this conception is that it allows us to see how different information can be gleaned from the same 'signal' given different starting points.

In the case of (2), we think naturally of a case in which an experienced vet in a well-organized office studies an x-ray known to be of Jackie, and learns that she has a broken leg. In another case, an experienced vet in a poorly organized office might infer from the x-ray and the fact that Jackie is the only dog in the place with a broken leg, that it was of her. And a would-be vet might learn how to read x-rays, knowing that the x-ray is of Jackie and that she has a broken leg.

Similarly, in (3) we think of a person who knows to which dog the vet refers when he says 'Jackie' and knows English, learning that Jackie has a broken leg. But attunement to the same constraint and a different starting point might allow someone to learn which of the dogs in the office was named 'Jackie'.

4 Accomplishments

Situation semantics has been used to analyse a wide variety of linguistic phenomena (see, for example, Gawron and Peters 1990; Cooper 1992), the liar paradox (Barwise and Etchemendy 1987), heterogeneous reasoning and representation (Barwise and Etchemendy 1991), diagrammatic reasoning (Shin 1990), the nature and structure of information and action (Israel and Perry 1990; Devlin 1991; Barwise 1993), and a number of other issues involving language, representation and computation.

It is probably fair to say, however, that up to this point situation semantics has been more successful in terms of adoption of its broad themes than in terms of adoption of its specific formalism and proposals. The main themes of early situation semantics (partiality, realism and the relational nature of meaning; see §1) have been incorporated into the (generally) received wisdom of philosophy and linguistics. But situation semantics remains only one of a number of alternative semantical frameworks that exhibit these virtues in various ways, from which a theorist may choose.

Semantics, teleological

Teleological/biological theories of meaning use a biological concept of function to explain how the internal states of organisms like ourselves can represent conditions in the world. These theories are controversial, as they have the consequence that an organism's history affects the content of its present thoughts. These theories have advantages over other naturalistic theories of meaning in the task of explaining the possibility of error and unreliable representation.

1 Basic ideas

Teleological/biological theories (hereafter, 'teleological theories') of meaning claim that certain internal states of organisms represent particular external conditions because of the biological *functions* of these inner states and mechanisms that interact with them. These functions derive from evolutionary history, or from some other history of selection; something's function is (roughly) the thing it does which explains why it is there (Wright 1973). For example, the function of the heart is pumping blood, as that is the thing hearts do that explains why they are there. Teleological theories of meaning, such as those theories of Millikan (1984) and Papineau (1987), apply this strategy of analysis to inner representational states (see Functional explanation).

These theories claim that inner states that help an organism coordinate its behaviour with its environment can represent environmental conditions that have played a certain causal role in the organism's history. For example, an animal may be put together in such a way that when a dark shadow appears overhead, an inner state occurs which causes the animal to hide. This inner state has the content 'Predator!' (or perhaps 'Danger!') if it is the presence of predators (or danger) on past occasions of this type that explains this pattern of inner wiring being favoured by natural selection. Similarly, though a frog might snap at any small dark object in its visual field, if the pattern of wiring responsible for this behaviour has been selected over alternatives because of past occasions in which this behaviour resulted in frogs obtaining food, then 'Food!' or perhaps 'Edible insect!' is the content of the inner state that is caused by the dark spot and which causes the behaviour. To use the language of Ruth Millikan (1984), who has developed the most sophisticated teleological theory, the inner state represents the environmental condition that must obtain for the state to help the parts of the organism that make use of (or 'consume') it to perform their functions in a historically normal way.

This type of explanation accounts for the content of belief-like states. The content of desire-like states can be explained in terms of satisfaction conditions. A desire's satisfaction condition is the condition in the world that the desire is supposed to bring about (see Belief; Desire).

Teleological theories do not hold that all beliefs or concepts have a specific evolutionary history. First, these theories can explain some novel beliefs as novel combinations of old concepts. Second, there can be teleological explanations of concepts that are not innate. Millikan explains the semantic properties of learned concepts in terms of the biological functions of parts of the cognitive system that are designed to adapt the organism to novel conditions by means of learning. An alternative approach, defended by Papineau (1987, 1993), is to view learning as a selection process itself, one akin to natural selection across generations, and an independent source of biological functions. In principle there are also other mechanisms which could bestow functions of the relevant sort, such as cultural evolution and deliberate design.

Though Millikan and Papineau give general analyses of all mental representation in these terms, it is also possible to use these ideas in less ambitious ways. A teleological theory could be used to explain only the most basic types of internal representation. Other theories of meaning could then make use of the representational abilities explained by the teleological theory (Sterelny 1990). For example, we might explain a basic stock of primitive concepts in teleological terms, and see more complex concepts as logical constructions out of these (an old-fashioned possibility). Or the teleological view might explain how it is possible for organisms to represent basic environmental features, including other organisms, and then social factors could be used to assign semantic properties to more complex thoughts and public representations. Either way, the teleological view would then be part of a package of different theories which work together in explaining meaning.

2 Related theories

One way to motivate the teleological view is by contrasting it to other naturalistic semantic theories. Indicator theories explain representation in terms of the existence of a reliable correlation, in certain conditions, between an inner state and its object (see Dretske 1981; Fodor 1990; Semantics, informational). These theories have difficulty explaining error and unreliable representation. Teleological theories are attractive to some because they allow an organism to represent something that it cannot, in principle, reliably detect. Suppose an organism's means of detecting predators is not reliable, as it is prone to 'false alarms'. No matter how unreliable it is, if this inner wiring was selected because it enabled organisms to escape predators, the inner state in question can be seen, on a teleological view, as about predators. For an indicator theory, the content of the inner state must be something weaker, which is reliably correlated with the inner state, such as dark shape. Although most teleological theories do assign these 'ecologically salient' states as contents of representations - 'Predator!' rather than 'Dark shape!' - this is not strictly necessary. Neander (1995) has defended a theory which is teleological in structure, but which converges with indicator theories in the contents it assigns in these cases.

Indicator theories are 'upstream-looking' theories; they link a representation to its object by looking to the processes involved in the bringing about of the representational state. They are based upon the organism's powers of discrimination by means of perception. Teleological theories look instead to connections 'downstream' of the representational state, connections going via behaviour and its consequences. In this respect there is a kinship between the teleological approach and some older ideas about thought associated with pragmatism (see Pragmatism). A simple way to link behaviour and belief content is to suppose that the truth condition of a belief is the condition such that actions based on the belief will be successful if and only if that condition obtains. The teleological approach is one way of developing this idea. It replaces the problematic notion of 'success' with a precise concept based upon natural selection. In some respects the debate between the indicator view and the teleological view is an expression of a more general opposition concerning the relative importance of perception and behaviour in understanding the mind. However, there have also been attempts to combine the indicator and the teleological approaches, such as the theory defended by Dretske (1988). For Dretske an inner state represents predators if it has the 'function to indicate' predators; both reliable correlation and function are required.

3 Current debates

Teleological theories of representation have been the subject of lively debate. I will discuss three types of objection.

First, these theories claim that organisms can only represent the world in virtue of facts about their history. Some find this unacceptable, as it entails that a molecule-for-molecule replica of you (such as the 'swampman' of Davidson 1987) which arose instantly by sheer chance would not have thoughts with any semantic content. Millikan's response is simply to embrace this result. Note that while an evolutionary history is required for content on Millikan's view, a more moderate line can be taken by theories such as Papineau's, which treat individual learning as an independent source of functions. Then a swampman would have no thoughts with content initially, but could acquire them within its lifetime.

Second, Jerry Fodor (1990) has argued that teleological theories cannot account for the 'opacity' of attributions of content (see Intentionality; Propositional attitude statements). Fodor claims that if all *F*s are *G*s in some environment, then anything that was selected in that environment for responding to *F*s was selected also for responding to *G*s. If so, attributions of content based on biological function cannot distinguish in such cases between representing the presence of an *F* and representing the presence of a *G*. Millikan replies that 'selection for' is a causal matter, and hence that attributions of function have as much opacity as causal explanations in general. Then teleological theories will distinguish between representing the presence of an *F* and representing the presence of a *G*, when all *F*s happen to be *G*s. The theories will only fail to distinguish between these two if the properties of being an *F* and being a *G* are indistinguishable in their causal powers. Then the question becomes whether a teleological theory ought to distinguish, for example, thoughts about equilateral triangles from thoughts about equiangular ones (see Causation; Property theory).

Lastly, suppose an organism avoids predators by avoiding some totally different environmental condition, such as sunrise, which happens to be reliably correlated with danger from predation (Pietroski 1992). Teleological theories say that the condition in the world with explanatory importance is the object of representation. So an animal that instinctively flees the sun and hence avoids predators is representing to itself 'Predator!' rather than 'Sun!'. This

can be so even if the animal has no ability to detect predators when they are right in front of it. This is a problem for most teleological views, including Millikan's and Papineau's, although not for Dretske's 'mixed' view nor Neander's theory. The problem is hard for standard teleological views because on such views there is not supposed to be a sharp distinction between the object of a representation and the object which explains the representational practice. These theories are explicitly aimed at assimilating the former to the latter.

Semiotics

As the study of signification, semiotics takes as its central task that of describing how one thing can mean another. Alternatively, since this philosophical problem is also a psychological one, its job could be said to be that of describing how one thing can bring something else to mind, how on seeing 'x' someone can be induced to think about 'y' even though 'y' is absent.

A person in whose head 'y' has been brought to mind may be responding to an 'x' someone else has transmitted with the intention of its signifying 'y'; or, mistakenly, responding to an 'x' someone has transmitted in the guileless expectation of its signifying some 'z'; or, often, responding to an 'x' that comes to his notice without anybody's apparent intention at all. Words, for example, generally signify because someone intends them to, and ideally (though not always) they signify what is intended; whereas clouds signify - a coming storm, a whale - because we so interpret them, not because they shaped themselves to convey some meaning.

Obviously the study of signification forms an integral part of the study of thinking, since no object can itself enter the brain, barring fatal mischance, and so it must be represented by some mental (that is, neural) 'x' that signifies it.

Signifiers are equally essential for creatures far lower than humans, as when a chemical signal 'x' emitted by some bacterium signifies to one of its colleagues some 'y' such as 'there's a dearth of food hereabouts'.

There are a number of ways in which an 'x' can signify some 'y', but for humans these are chiefly: by physical association; by physical resemblance; and/or by arbitrary convention.

When we take some 'x' as signifying some 'y' we are often guessing; our guess is subject to checking by interpretative (re)appraisal.

1 The signifier, the signified, the appraisal

In what might be called the standard version of semiotic theory, which in most essentials we owe to the American polymath Charles S. Peirce, our knowledge of the external world, in fact all thinking of any kind, is composed of chains and skeins of linked representations or signifiers ('signs' for short). The world enters our consciousness as highly processed sense-reports, which begin as representations (for instance, the electro-chemical signals into which our light-recepters transform the light striking the retina). So the world is understood, to the extent that it is, via signs, many of which stand for still other signs, each bound to what it signifies by interpretive (re)appraisals, which take account of such things as general knowledge and immediate context. An illustrative example of such a skein of signs is provided by the various ways in which an English word can be encoded. In Morse code the word 'card' is ' —·—· ·— ·—· —··', where, to take just the first Morse letter, ' —·—·' stands for:

(1) the relatively long and short electrical impulses we call 'dash, dot, dash, dot' (thus sequenced);
(2) the relatively long and short audible beeps we call 'dash, dot, dash, dot' (thus sequenced);
(3) the words 'dash, dot, dash, dot' (thus sequenced);
(4) the Roman letter 'C';
(5) the sound that 'C' spells in the context '-ard', namely /k/.

Each of these stands, in turn, for any or all of the others. Even this is but a bare beginning, since the entire word 'card', however expressed, stands ultimately for a concept, which interpreted or appraised in a particular context might be a playing card, a visiting card, an index card or part of a machine for carding wool.

Though he had many eminent predecessors, it was Peirce who first undertook, in plangent insights scattered over his (mostly unpublished) eighty-odd volumes of papers, to build a comprehensive discipline of semiotics within which all varieties and manners of signification could be given a unified explanation. He entered his final decline with this mighty task unachieved, but he had at least clearly delineated the framework within which almost all semiotic issues, even the semiotic investigations of antiquity, are currently best understood. In particular, it was Peirce who first definitively gave equal triadic footing to the signifier, what it signifies and its interpretative (re)appraisal.

The two greatest semiotic theorists of antiquity were Aristotle and Augustine, with other important contributions from Plato and the Greek Stoics, especially Chrysippus (see Language, ancient philosophy of). Taken as a group, these philosophers distinguished with some care, first, between '*x*' the signifier and '*y*' what it signifies and, second, between the signified '*y*' and, where at issue, the object in the putatively real world that '*y*' represents (Plato, primarily in *Cratylus*; Aristotle, most importantly in *De Interpretatione (Perihermenias)*; Chrysippus; and Augustine in *De Doctrina Christiana*). In addition Aristotle established in the *Prior Analytics* that in the process by which sign is tied to signified, the determination of what the sign signifies is often a probabilistic guess. If I interpret the apparent fact that 'That weathervane is pointing north' as signifying that 'The local wind is a northerly', I am jumping from premise to conclusion without invoking the universal premise ('A north-pointing weathervane *always* signifies that the local wind is a northerly') that would clinch this enthymeme as a syllogism. (Note that here, as so often, 'signifies' functions like 'implies'.) In fact this missing universal premise is quite properly omitted, since it is false. Weathervanes sometimes mislead. They can be rusted in place; be under the control of mischievous children; be indicating, in the absence of any more recent wind, the direction from which it blew a day ago. In short, once a sign like a weathervane's pointing north has been guessed to be signifying a current local northerly, there is much room left for an interpretative (re)appraisal of such vital facts as the presence or apparent absence of mischievous children.

Chrysippus nicely demystified the tie between the signifier and what it signifies by arguing that any such tie is made in the mind. (He so emphasized this point, in fact, as to hold that the tie itself is the *only* mental entity, since for him both signifier and signified - his *semenon* and *semenomenon* - were real things in the real world. Whereas nowadays we recognize that it is not the weathervane itself that signifies to us, but our mental image of it. If its image is lacking, the weathervane has not even been seen.)

It was well recognized in antiquity that, while words may be the archetypical signifiers, many signifiers are not words. Aristotle, for instance, mentions in the *Prior Analytics* that a woman's lactating constitutes a sign (it signifies that she is pregnant); and Augustine, to take another instance, writes in *De Doctrina Christiana* of footprints as signs (of the passage of whoever owned the feet). In this fashion the groundwork was laid for a general science of signs, that is, for semiotics.

Interest in signs and their relations continued during the medieval and early Renaissance periods, notably among the many who seem to have devoted the bulk of their waking hours to writing exegeses of Aristotle. These activities centred, for reasons partly accidental, in Iberia: in Portugal (Fonseca, P. da and John of St Thomas, also known as Jean Poinsot) and, in an earlier and more arcane outbreak, in Catalonia (Llull, R.). Although this work retains much historical interest, it added little to semiotic theory, perhaps because so much of it was devoted to weighing in on one or another of the theological or quasi-theological debates that in those days took the place of free inquiry. With the full Renaissance, however, and the rebirth of interest in everything human, interest in semiotic problems occasionally took a different and more organized turn, notably in the work of George Dalgarno of Scotland (*c*.1619-87).

2 Modern developments

The next important advances came in the late nineteenth and twentieth centuries. First, Charles S. Peirce codified Aristotle's notion of enthymemic signification into the trivium: 'sign' (signifier) + signified objective (which Peirce unfortunately shortened to 'object') + 'interpretant'. It is worth especial notice that Peirce's 'interpretant' plays an essential role in his system, since for him (as for Aristotle) many and perhaps most signs are understood to be tied to their object(ive)s by probabilistic guesswork - by the intuitive leap that Peirce called 'abduction' - requiring the amplification and partial (de)confirmation available, with luck, from an appraising interpretant. More importantly, in Peirce's codification each such interpretant is often itself a sign and so in turn is tied to some signified object, or perhaps to more than one such, each being in need of a still further interpretant, and so on, in some cases *ad infinitum*. In this fashion Aristotle's enthymemic sequence of (minor premise) + (consequent) + (probabilistic substitute for the missing major premise) is converted into a unified chain of signs, each engaged in a triadic structure of sign + object + interpretant.

The three most important theorists since Peirce have been Charles Morris (1901-79), Thomas A. Sebeok (b.1920), and Umberto Eco (b.1932).

Morris' chief contribution was to put living flesh on Peirce's 'interpretant', which for Peirce was a discarnate or at least incorporeal activity - 'pure mind' perhaps - but which for Morris was an interpreter with a brain and a body. This is a gain, since who or what produces and interprets signs has a physical shape that can influence how signs are shaped and related to other signs. (Simple example: the deaf 'speak' their signs with their hands, face and torso; and, compared to vocal signs, the signs of the deaf are predictably different in form, in their modifiability, in their mutual resemblances, and in the ways in which they can mimic what they signify.) Similarly, the primary signs that begin the process of someone's assigning to some sign some significance - the process that is nowadays called 'semiosis' - are for Morris real and observable 'sign-vehicles' of interest in their own right. Both points are important, because how signs are emitted and received by physical entities (such as bodies and brains), and how the signs of a given system (such as the English language) are structured and inter-related, are topics to which Peirce himself gave short shrift. The distinction between corporeal and discarnate semiosis can be summed up in two terms: 'pragmatics' versus 'pure rhetoric', respectively Morris' and Peirce's terms for the study of how signs are related to their interpretants.

Thomas Sebeok's effect on semiotics as a field of study has been pervasive, and is universally recognized. He was co-founder (with Margaret Mead) of the modern semiotic discipline (in 1962); he was founding editor of the defining journal *Semiotica* (from 1968); and he has been the guiding mentor to the entire field. His theoretical contributions are likely to prove just as lasting. He has steadily broadened the scope of semiotic inquiry, for instance by delving into zoösemiotics (the study of infrahumans' signifying activities, in both fact and myth, and of their 'prefigurements of art') and into the sub-area of endosemiotics (the study of signifying among microbiota, neurons included). He has sharpened some of Peirce's most basic notions (see §3) and he has opened the eyes of many to the necessity of defining the logical nature of the basic connective 'signifies' (or 'is a sign of'), as by noting that that connective must be at least potentially reflexive and symmetric.

Umberto Eco, besides having written the 'semiotic' novels that have brought him deserved fame, has been deeply involved in the development of semiotic theory since the late 1960s. He is the author of well-known basic texts, has written on the history of semiotic inquiry and has striven to refine some of Peirce's fundamental concepts.

Among the many other twentieth-century scholars who have also made noteworthy contributions to this burgeoning field are Ferdinand de Saussure, Jacob von Uexküll (1864-1944), Karl Bühler (1879-1963), Roman Jakobson (1896-1982) and Louis Hjelmslev (1899-1965) (see Structuralism in linguistics).

3 Signifying by association, by resemblance, by convention

A given sign may do its signifying in different ways: in the widely used terminology laid down by Peirce, it may signify by physical association with what it signifies (such signifiers are called 'indexes'); by mimicry, that is, by physical resemblance to it ('icons'); and/or arbitrarily and merely by convention ('symbols'). For instance the sketchy representation of a man found on certain urgently sought doors in airports indicates by physical association (location) that this and not the next one is the door to the men's toilet; it indicates by recognizable physical resemblance to a man that this door leads to the men's facility (and not the women's); and it indicates the latter fact partly by convention, since generally it is a stick-figure with a pumpkin head and bears little resemblance to an actual person.

This three-way distinction of types of sign was first drawn by Augustine (*De Doctrina Christiana*), though the distinction between imitative icon and arbitrary symbol, or between symbol and associative index, had been hinted at earlier, respectively by Plato (especially *Cratylus*) and Aristotle (*Prior Analytics*). The distinctions are clear enough in theory, but their application is sometimes aporetic, as when deciding the extent to which a word like 'ding-dong' is imitative (hence 'iconic' in Peirce's sense) or arbitrary (hence 'symbolic'). Indeed, as Plato showed, albeit inadvertently, such discussions are often inconclusive or plain silly. (He argued in *Cratylus* that no Greek noun could be wholly arbitrary, unless imported from Phrygian or some other barbarian language, since any native Greek word could be partitioned, in the crackpot philology of the time, into meaningful subsegments.)

The ternary division of sign-types has a broad acceptance, though alternatives are possible. Certainly a binary division is conceivable - for instance, into Saussure's 'arbitrary' and 'non-arbitrary' types, the latter including both the iconic and the indexical - and it is not difficult to add a fourth or even fifth sign-type. One such is the sign that signifies by modelling the physical process of producing its real object, as the characters of the Korean Hangul

writing-system do (they model the mouth in the act of articulating the characters' corresponding sounds).

On the other hand, Peirce's basic tripartite division of sign-types seems quite robust in comparison with some of the other categorizations that have been proposed. For example, in George Dalgarno's tripartite typology, the earliest fully coherent one (in *Didascalocophus* (1680)), three kinds of signification are defined, but by such a hotchpotch of criteria as to leave the categories leaking rather badly. Dalgarno reserves 'conventional' signs (Peirce's 'symbols') for the exclusive use of humans, and 'natural' signs (Peirce's 'indexes') for infrahumans; supernatural signs, such as 'dreams' and 'apparitions' (these correspond to nothing in Peirce's basic typology) he reserves for the use of 'Almighty God'. (This last category is consistent with the pervasive belief in theurgy typical of Dalgarno's day, but it may have sprung from one of the more bizarre passages in *Cratylus*, where Plato avers that the gods have their own language. Proof: they call 'Xanthus' the river that humans call 'Scamander'.) Dalgarno would thus implicitly deny to humans the ability to signify anything by indexes (such as by correctly placing the 'men's toilet' sign) or, presumably, by such humanly transmitted 'apparitions' as plays or films.

4 Systematicity

Signs typically fall into sets, each sign sharing with its fellows distinctive properties of similarity of form and/or function. Thus the words of English are similar in their partaking of the English sound-system (so that a French word, if properly pronounced, cannot be an English word). Again, any arrangement of signs properly called a sentence is only the overt aspect of one or more covert underlying structures. The sentence: 'Politicians who hold floozies to be congenial are likely to be denounced from the pulpit', can be assigned either of two rather different structures and corresponding meanings. In one, certain politicians embrace floozies in order to be congenial; in the other, it is to the floozies that congeniality is attributed, by certain politicians (see Ambiguity). Such structures have been paid far more attention by linguists than by other semioticists, partly because they are presumably more intricate in language than elsewhere; but, clearly, some other systems of signification have intricacies of their own (think of a map of the London Underground), and much remains to be done.

Another way in which signs are parts of systems is this: the connective 'signifies' has logical or functional properties, which when well defined may be uniform. While the colloquial verb 'signifies' does not map neatly into a single logical connective, any more than the colloquial verb 'implies' does, much is gained by pondering this issue. As a defined propositional connective, 'signifies' is functionally equivalent to 'implies' or even 'if and only if'. For instance, when 'signifies' is narrowly defined then '(*p* signifies *q*) & (*q* signifies *r*)' signifies '*p* signifies *r*'. (Let '*p*' = 'that weathervane points southward', '*q*' = 'the local wind is southerly', and '*r*' = 'it will soon warm up'.) However, 'signifies' as a nominal connective is rather different. From 'this drawing signifies that cloud' & 'that cloud signifies an impending storm' it certainly does not follow that therefore 'this drawing signifies an impending storm'. Two different meanings of 'signifies' are being played on here - 'represents' and 'betokens' - and mixing them must often produce nonsense.

This said, it remains to observe that the construction of a comprehensive semiotic calculus is very much a work-in-progress.

5 The field

As presently constituted, the field of semiotics exists less as a discipline than as a speciality. The process by which someone receives or emits a sign, and interprets or conceives it - the process generally called 'semiosis' - is investigated by both semioticists and psychologists, mainly in a domain such as the processing of language, whether written or spoken. (In earlier semiotic work issues of semiosis were rather slighted, apart from some inconclusive remarks by Peirce on, for example, the 'firstness' (roughly, accessibility without mediation) of sense-impressions. This is nice, but it sharpens only slightly Augustine's pellucid definition of a sign as 'a thing which, over and above the impression it makes on the senses, causes something else to come into the mind as a consequence of itself' (*De Doctrina Christiana* 2.1.1).) The functioning of signs in literature, music, architecture, painting and drama is mainly pursued by semioticists who are also students of those respective arts. Examples of work in these and other areas of semiotics can be found in the references.

Seneca, Lucius Annaeus (4/1 BC-AD 65)

Lucius Annaeus Seneca, Roman statesman and Stoic philosopher, is the earliest Stoic of whose writings any have survived intact. Seneca wrote, in Latin, tragedies and a wide range of philosophical works. His philosophical and literary work was carried out in the intervals of an active political career. He is most important for his ethics and psychology, although natural philosophy was not neglected. Unlike many Stoics he showed little interest in logic or dialectic. His most influential work was on the psychology of the passions, the nature of the human will and techniques of moral education; he also wrote extensively on social and political issues from a distinctively Stoic perspective.

1 Life and works

Seneca was born into a wealthy family of the equestrian class at Cordoba in Spain. His father, the Elder Seneca, saw to it that his son was educated at Rome, where he rose to become a senator. Exiled and recalled by the emperor Claudius, Seneca became the teacher and advisor of the emperor Nero. His influence on Nero was considerable until AD 62; Seneca eventually withdrew from active politics, but nevertheless was compelled to commit suicide in AD 65 for his presumed support of a conspiracy against Nero.

Seneca's Stoicism was affected by his early adherence to the Sextian school of philosophy (see Neo-Pythagoreanism), which emphasized asceticism and moral training. His Stoic education was thorough, and his works reveal the influence of Panaetius, Hecaton and Posidonius as well as the early heads of the school (see Stoicism §1). He rethought many aspects of Stoic philosophy and continued the work of Cicero in developing a Latin philosophical vocabulary. His prose writings display a balance between his personal contribution and inherited school doctrine. He was a part of contemporary literary culture, famous for his distinctive rhetorical prose style and as the author of justly admired tragedies. The relationship between his philosophical convictions and the tragedies is controversial, as is the question of the impact of his philosophical convictions on his political activity.

Many of Seneca's works are lost, including a biography of his father, speeches, letters and a late treatise entitled *Moral Philosophy*. His surviving prose works include three consolatory works, *To Marcia*, *To Polybius* and *To Helvia* (his mother). Most of his treatises on ethics were dedicated to close friends or family members, although *On Mercy* was addressed to Nero. Also of political note is a viciously witty satire on the dead emperor Claudius, the *Pumpkinification*. Late in his career Seneca wrote a lengthy work on physics, the *Natural Questions*.

The other extant ethical works are: *On Anger* (in some ways a companion piece to *On Mercy*); *On the Brevity of Life*; *On the Steadfastness of the Wise Man*; *On Mental Tranquillity*; the fragmentary *On the Private Life*; *On the Happy Life*; the long treatise *On Favours*, which deals with social relations as well as personal ethics; the fragmentary *On Providence*; and his most influential work, the *Letters to Lucilius* (more correctly *Letters on Ethics*, henceforth *Letters*).

Seneca is important for the history of Stoicism because he is the earliest professed Stoic any of whose works survive in complete form. It is not his aim to report on the history of the school, and his evidence for its early period must be used with care. His treatises confirm and elaborate on what is known about early Stoicism from other sources, but divergences and changes of emphasis are not uncommon. Examples of this include the treatment of a political figure, Cato the Younger, as a sage; an emphasis on suicide as the ultimate expression of personal freedom; and a humane application of the traditional Stoic view that there are no natural slaves.

Seneca's philosophical works have been persistently influential, first on Latin Church Fathers and again in the Renaissance; Montaigne's *Essays* owe much to Seneca's *Letters* (see Patristic philosophy; Montaigne, M.E. de; Renaissance philosophy).

2 Psychology

Seneca's greatest contribution is in moral psychology. In numerous works it is apparent that personal moral decision (*voluntas* or 'will') is given greater emphasis than it received in earlier Stoicism. The treatise *On Anger* (especially book II) also suggests (although this is a controversial point) that he has rethought the earlier Stoic

theory of assent and reassessed its role in the explanation of passions. He treats assent as a consciously made decision, a moment of personal self-assertion which shapes (rather than just reveals) our moral character. Will, for Seneca, has become the focus of individual moral freedom, much as *prohairesis* was to be for Epictetus (§3). It would be extreme to say that Seneca has posited a distinct faculty of 'will'; but he certainly took some steps in that direction and inspired others, such as Augustine, to go even further.

His views on the relationship between reason and the passions are also of note. He held to the view that passions are produced by the rational mind when it makes errors about the values of things, and denied the claim of Plato (§14) and Aristotle (§§22-3) that they are rooted in a non-rational part of the soul. Seneca did, however, take an interest in the complexity of the interactions between bodily reactions to external stimuli and our mental responses to them. His psychology may sometimes seem Platonic, but if there is 'dualism' in his theory, it is the body-soul dualism of Plato's *Phaedo* rather than the psychological dualism of the *Republic* (see Plato §§13-14). Hence Seneca rejected the Peripatetic view (see Peripatetics) that passions should merely be moderated; *apatheia*, complete freedom from passions, remained the ideal.

3 Ethics, physics, logic

Seneca emphasizes that he is not himself a wise man, but merely a *prokoptōn*, a person making moral progress. Like other Stoics of the first century AD and like Panaetius two centuries earlier, he focuses on the moral needs of his audience of imperfect but serious students of philosophy, rather than on the somewhat abstract deductions of earlier theorizing. The paradoxical technicalities of Stoic ethics are not unknown to Seneca, however; in the treatise *On Favours* he applies them effectively to serious ethical questions.

Seneca's attitude to physics is typical of his time, and is important as background to ethics: one must grasp the basic outlines of a providentially organized cosmos held together by a divine plan with which mankind is in harmony, but detailed debate about physics and cosmology is not worth much effort. Specific phenomena, such as those explored in the *Natural Questions*, are dealt with out of scientific curiosity or as illustrations of the divine rationality of the world we inhabit. Logic and dialectic are almost entirely neglected by Seneca. He was aware of work in this area, but comparison with Epictetus shows Seneca's limitations in logic (see Epictetus §2).

4 Seneca and philosophy in the first century AD

Seneca's works provide us with an invaluable picture of philosophical life in Rome in the first century AD. His reaction to Epicureanism (which ranges from selective appreciation in the early books of the *Letters* to the hostile denunciations of *On Favours* 4) shows that the school was still to be taken seriously. Similarly, *Letters* 58, 65 and 89 show that Seneca was familiar with the more technical doctrines of contemporary Platonic and Aristotelian philosophy, just as *Letters* 121 and 124 display his detailed knowledge of the technical side of Stoic ethics. Cynic philosophy was important in Rome, and Seneca anticipates Epictetus in his attitude to it: a Cynic (such as Seneca's friend Demetrius) can be presented as a paradigm of the wise person, despite the Cynic rejection of physics and logic as areas of study.

5 The *Letters*

The *Letters to Lucilius* have proved the most influential of Seneca's works. The dedicatee, Lucilius, was a real person, but the letters are fictitious, philosophical open letters modelled on those of Epicurus and designed to emulate the published correspondence of Cicero. Seneca plays the role of a moral advisor to Lucilius, whose progress can be followed through the sequence of letters. The tone and style of the letters also owes much to the rhetorical form known as the diatribe (see Cynics §3), and is often similar to that of his moral treatises; but there is a greater fluidity and intimacy. Although the facade of epistolary realism is often dropped, Seneca's pretence of writing to a close personal friend draws the reader into a personal engagement with Stoicism that could not otherwise be achieved; finely judged autobiographical revelations and confessions sustain a sympathy for Seneca as a moral teacher which is not evoked by the rest of his works. The *Letters*, in fact, paved the way for the development of the personal philosophical essay as a genre.

The *Letters* as we have them culminate with an investigation of a technical problem in Stoicism: is 'the good' grasped by the senses or by the intellect? Beginning with a quotation from Virgil, Seneca guides the reader through the complexities which establish that the genuine good is grasped by the mind and can only be found in a

rational soul. That rational virtue is the only good is a view fundamental to Stoic ethics, yet detailed physical and metaphysical argument is required to establish it. The reader is soothed by the literary grace of Seneca's style; the strategy of personal address promotes personal conviction. Seneca goes beyond Lucretius, who claimed to mask the bitterness of philosophical technicality with the honey of his poetry. However, Seneca used the tools of his literary art not to disguise the philosophy we must swallow, but to draw us as willing participants into its inner workings. Like the best of Plato's dialogues, Seneca's letters exploit the illusion of personal dialogue to make us partners in his own search for wisdom.

BRAD INWOOD

List of works

The dating system used below follows Griffin (1992); *On Providence*, being fragmentary, is hard to date with accuracy.

Seneca, L.A. (late 30s AD) *Consolation to Marcia*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; addressed to the daughter of the historian Cremutius Cordus.)

Seneca, L.A. (40s AD, during his exile) *Consolation to Polybius* trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; in part an attempt to regain favour at the court of Claudius.)

Seneca, L.A. (40s AD, during his exile) *Consolation to Helvia*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; addressed to his mother, concerning his own exile.)

Seneca, L.A. (before AD 52) *On Anger*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1917-25, 10 vols.(Latin text with facing translation; especially important for Stoic theory of passions.)

Seneca, L.A. (*c*. AD 48-55) *On the Brevity of Life*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1928.(Latin text with facing translation; life is long enough for one guided by philosophy.)

Seneca, L.A. (*c*.50s) *On the Steadfastness of the Wise Man (De constantia sapientis)*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1928.(The wise man is immune to insult and injury.)

Seneca, L.A. (*c*.50s) *On Mental Tranquillity*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; Stoic rationality as the key to contentment.)

Seneca, L.A. (*c*.50s) *On the Private Life*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; on the relation between political and philosophical life.)

Seneca, L.A. (*c*.50s) *Pumpkinification (Apocolo-cyntosis)*, trans. W.H.D. Rousé, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1917-25, 10 vols.(Latin text with facing translation; satire on the emperor Claudius.)

Seneca, L.A. (*c*.50s) *On Mercy*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1928.(Latin text with facing translation; important for political theory as well as ethics.)

Seneca, L.A. (*c*.50s) *On the Happy Life*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1932.(Latin text with facing translation; a vigorous defence of the Stoic conception of life according to nature.)

Seneca, L.A. (*c*. AD 56-62) *On Favours (De beneficiis)*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1935.(Latin text with facing translation; general theory of social relations and ethically appropriate action.)

Seneca, L.A. (by AD 64) *Natural Questions*, trans. T. Coscoran, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1971-2.(Latin text with facing translation; essays on a range of topics in natural philosophy with ethical digressions.)

Seneca, L.A. (*c*. AD early 60s) *Letters*, trans. R.M. Gummere, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1917-25, 10 vols.(Latin text with facing translation.)

Seneca, L.A. (*c*. mid 1st century BC) *On Providence*, trans. J.W. Basore, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1928.(Latin text with facing translation.)

Sengzhao (AD 384?-414)

Sengzhao was one of the first native Chinese thinkers to develop a distinctive version of Buddhist philosophy. He blended the dialectical logic of Indian Mādhyamika Buddhism with ideas and terms often borrowed from Chinese Daoism. His collected treatises, the Zhaolun, argued that language is inadequate for capturing reality. There is a need for an intuitive insight to penetrate reality in its nonlinguistic form as a means to understanding the process and limitations of subsequent conceptualization.

Born in Changan (present day Xian) in AD 384 (or possibly 374), Sengzhao was from a poor family and found work as a copyist, an occupation that gave him broad exposure to a variety of literatures. Originally enamoured of the neo-Daoism popular at the time, Sengzhao converted to Buddhism after reading a copy of the *Vimalakīrti Sūtra*. As a Buddhist monk in northwestern China and then in Changan, he studied under the famous Indian Buddhist translator and commentator Kumārajīva (AD 344-413). Kumārajīva introduced Sengzhao to Mādhyamika thought, known in China either as the 'Four Treatise School' or the 'Three Treatise School' (see Buddhism, Mādhyamika: India and Tibet). As a chief disciple of Kumārajīva, Sengzhao achieved great eminence and his writings have been regarded as foundational to the Sinicization of Indian Buddhism.

Sengzhao's contribution to Chinese philosophy had multiple dimensions. First, he introduced a new form of rhetoric for philosophical argument. In this regard, Sengzhao often used models of argumentation taken from the second-century founder of Indian Mādhyamika philosophy, Nāgārjuna. Nāgārjuna had developed a form of dialectical analysis to show that opposing concepts could only be understood in relation to each other. Yet, the realities to which they referred were typically considered ontologically discrete. For example, the concepts of 'past', 'present' and 'future' are understood in terms of each other, yet the realities to which they supposedly refer cannot temporally coexist and, therefore, cannot be directly related. So, Nāgārjuna argued that the way concepts interrelate cannot mirror the way their supposed referents interrelate. Sengzhao assimilated aspects of this form of argument in analysing pairs of concepts. However, he did not always analyse the same pairs of concepts as had Nāgārjuna. Often his arguments seemed to address issues more central to the indigenous concerns among the neo-Daoist philosophers, for example. In this regard, it is important to note that some of Sengzhao's dialectical style of analysing opposing pairs of concepts also resembled the form of argument in Chapter Two of *Zhuangzi*, the famous Daoist philosophical classic (see Zhuangzi). Therefore, Sengzhao was developing a form of argumentation that drew on both Indian and indigenous Chinese traditions. This may account for the almost immediate reaction of his contemporaries that he had introduced a new and important style of philosophical argument.

Second, and closely related to the first point, Sengzhao's writings heightened the Chinese awareness of the logical structure of argumentation. Sengzhao did not seem to have a logician's grasp of the principles involved in Mādhyamika argumentation, sometimes making invalid inferences in his arguments. It is likely that he did not have access to Indian logical treatises. Therefore, without the help of theoretical explanation, he probably developed his logical arguments by trying to mimic the style of Mādhyamika writings. Despite this limitation, he often formulated arguments with a logical tightness that had not been attained previously by Chinese writing in their native language. This set the stage for further Chinese developments in this area as the Chinese Buddhists learned more of the Indian forms of rhetoric and logical analysis.

Third, Sengzhao gave the Mādhyamika idea of intuitive insight (*prajñā* in Sanskrit; *banru* in Chinese) a new explication. As in the Indian tradition, this intuitive insight was considered an immediate, perhaps mystical, grasp of reality without the intervention of conceptual understanding. One important difference from the Indian tradition, however, was that Sengzhao associated this intuitive insight with the Chinese tradition of the sage. In various indigenous philosophies, the Chinese sage had been described as having extraordinary powers of insight into reality. Sengzhao identified this quality with the Buddhist ideal of intuitive insight. This had the effect of making Chinese Buddhism, like Daoism and Confucianism, a 'sage religion'. Furthermore, it reinforced the indigenous idea that an immediate experience of reality was possible. Sengzhao stressed that since this intuitive insight did not have a conceptual object, it could not be a form of knowledge. It was something more 'spontaneous' or 'natural' than conceptual modes of apprehension. This emphasis on merging with the natural gave the Buddhist idea a

distinctively Daoist flavour (see Daoist philosophy §1; Zhi).

Lastly, although Sengzhao stressed the primacy of intuitive insight, he also stressed the dual-layered character of reality. On one level, there is a natural, organic source that can be grasped immediately. On another level are the functions of that source as the realm of conceptual expression, yielding a necessary but limited grasp of truth. This gave Sengzhao's Chinese Buddhism an emergent or process form of ontology describing how the non-conceptual became conceptualized. This organic model of reality was not present in the Indian Mādhyamika tradition and was much closer to ideas in Daoism and such ancient Chinese Classics as the *Yijing* (see Yijing).

Because of these varied dimensions to Sengzhao's work, scholars disagree about the best way to classify his own philosophical perspective. Was Sengzhao essentially a product of the Chinese, fundamentally neo-Daoist worldview who managed to graft on to the tradition some new rhetorical structures imported through Indian Buddhism? Or was he a convert to the Indian philosophy of Mādhyamika Buddhism who was able to stretch his native language and indigenous ideas to accommodate the new way of thinking he had adopted? Or was he a creative, syncretistic thinker who developed his own distinctively cross-cultural philosophy? Because his writings are not extensive and because he was breaking out of the boundaries of the traditional styles of writings, some critical points are open to multiple interpretation. What is undisputed, however, is Sengzhao's impact on the ensuing Chinese philosophers of various schools.

(Good scholarly study of the Mādhyamika tradition, including a chapter on Sengzhao and a translation of three fascicles of the *Zhaolun*.In contrast to Liebenthal, Robinson emphasizes Sengzhao as a continuation of the Indian Mādhyamika tradition.)

Sense and reference

The 'reference' of an expression is the entity the expression designates or applies to. The 'sense' of an expression is the way in which the expression presents that reference. For example, the ancients used 'the morning star' and 'the evening star' to designate what turned out to be the same heavenly body, the planet Venus. These two expressions have the same reference, but they clearly differ in that each presents that reference in a different way. So, although coreferential, each expression is associated with a different 'sense'. The distinction between sense and reference helps explain the cognitive puzzle posed by identity statements. 'The morning star is the evening star' and 'The morning star is the morning star' are both true, yet the sentences differ in cognitive significance, since the former may be informative, whereas the latter definitely is not. That difference in cognitive significance cannot be explained just by appeal to the references of the terms, for those are the same. It can, however, be naturally accounted for by appeal to a difference in sense. The terms 'the morning star' and 'the evening star' used in the first sentence, having different senses, present the referent in different ways, whereas no such difference occurs in the second sentence.

The distinction between sense and reference applies to all well-formed expressions of a language. It is part of a general theory of meaning that postulates an intermediate level of sense between linguistic terms and the entities the terms stand for. Senses give significance to expressions, which in and of themselves are just noises or marks on a surface, and connect them to the world. It is because linguistic terms have a sense that they can be used to express judgments, to transmit information and to talk about reality.

1 Sense, reference and cognitive significance

The distinction between sense and reference was originally drawn by Gottlob Frege in his 1892 article 'Über Sinn und Bedeutung' ('On Sense and Reference'; see Frege, G. §3). According to Frege, associated with each meaningful expression of a language there is a 'sense' (*Sinn*) that makes the expression significant and determines its 'reference' (*Bedeutung*), that is, the entity the expression applies to or designates. ('*Bedeutung*' is also translated as 'designation', 'designatum', 'denotation' and 'nominatum'. It is also sometimes translated as 'meaning'. This can create confusion, since some of Frege's contemporaries, including Russell, used 'meaning' as the translation of '*Sinn*', most likely on the assumption that the notion corresponding to '*Sinn*' is that of cognitive meaning or significance.) Before 1892, Frege had espoused the view that the significance or content of an expression is given exclusively by that which the expression designates or stands for (what he came to regard as the 'reference'). Observe that on such a view two coreferential terms, such as 'Cicero' and 'Tully', are supposed to have the same content or significance. But if that is so, it seems impossible to explain the obvious difference in cognitive significance between, say, 'Cicero is Cicero', a trivially true and uninformative statement, and 'Cicero is Tully', a potentially informative sentence. The problem of how to explain differences in cognitive significance is not restricted exclusively to statements of identity. 'Cicero was an orator' and 'Tully was an orator' also differ in cognitive significance, since it is possible for a competent speaker to accept one of the statements while rejecting the other. Without postulating a difference in the content or significance of the terms 'Cicero' and 'Tully', it would seem impossible to explain the differences between those two pairs of sentences. The distinction between sense and reference provides for a natural explanation: although the two names are coreferential, they are associated with different senses and those senses present the referent in different ways (see Proper names §1).

2 The sense and reference of different types of expressions

The distinction between sense and reference is intended to apply to all meaningful expressions of a language, whether simple or complex. In the case of definite descriptions it is an extremely natural distinction since it is obvious that different descriptions of one and the same object present that object in different ways. In the case of proper names, the reference is the bearer of the name and the sense is traditionally conceived as some sort of condition satisfied uniquely by the referent. There is no unanimity, however, regarding how to understand such a uniquely identifying condition. Frege suggests (1892) that the sense of a proper name is some descriptive information that applies uniquely to the bearer. Thus, some philosophers interpret Frege's suggestion as entailing the claim than each proper name is synonymous with some definite description. Others, including John Searle (1958), view the sense of a given proper name as a cluster of descriptive information that speakers associate with

the name, and the referent as whatever satisfies most of the attributes in the cluster. Other semanticists do not uphold the descriptive nature of the senses of proper names. For example, David Kaplan (1969) has argued that on Frege's view the sense of a name may be seen as a representation of the referent and so the relation between the sense of a name and its reference is much like the relation between picture and pictured object. Finally, Michael Dummett (1981) is the foremost representative of the view that regards the sense of a proper name, as the sense of any expression, as a mechanism or procedure that, under ideal circumstances, would enable a competent speaker to single out the referent.

The reference of a general term is traditionally taken to be the extension of the term in question. Thus, for example, in the case of a predicate such as 'red' the extension is the set of red things, that is, the set of things to which the predicate correctly applies. And the extension of a relational verb such as 'is taller than' is a set of ordered pairs (since 'being taller than' is a relation between two things) such that the first member of each pair is taller than the second member of the pair. The sense of a general term is a mode of presentation of the set and is responsible for the cognitive content or cognitive significance of the term.

Although it is traditional to represent the reference of a general term as a set, such a choice is strictly incorrect, from the standpoint of pure Fregean orthodoxy. Frege distinguished sharply between concepts and objects. Only the latter are, on his view, 'saturated' entities; entities that subsist on their own. People and artefacts, also numbers and sets, are saturated entities. On the other hand, concepts are 'unsaturated'; they do not have an independent existence, but can only subsist as completed by a saturated entity. On Frege's view, the reference of a general term is a concept, and thus an unsaturated entity. Thus, the reference of a general term is not a set, for the latter is a saturated entity. Still, in the posthumously published comments on 'Über Sinn und Bedeutung' (1892-5), Frege himself stresses that any two general terms refer to the same concept just in case their extension is the same. So, it seems that, even for Frege, equality of extension is a criterion of identity for concepts, so taking the reference of a general term to be a set is not a radical departure from the standard Fregean theory.

Finally, according to the theory, whole sentences express complete thoughts. The 'thought' or sense associated with a sentence is the claim or assertion, traditionally called the 'proposition', expressed by the sentence. In 'Über Sinn und Bedeutung' Frege argues that the sentence's reference is its truth-value. The relation between a sentence and its truth-value should therefore be understood in terms of the relation between a name and its bearer or a definite description and the individual it designates. A true sentence is like a name for 'True', so that all the true sentences (like all the false ones) have one and the same reference; however, since different, non-synonymous sentences express different thoughts, they present that reference in different ways. Frege's argument relies on the assumption (see §4 below) that the reference of a complex expression does not change if components with the same reference are intersubstituted. Thus, for example, if we substitute the coreferential 'the orator who denounced Catiline' for 'Cicero' in the complex expression 'the father of Cicero', the reference of the expression (whoever fathered the famous orator) does not change. In this vein Frege asks what it is that remains constant when we intersubstitute coreferential components in a sentence, for that should be the reference, if anything is. He observes that the thought cannot be the reference, for typically the thought expressed by the sentence is altered: 'Cicero was an orator' and 'The orator who denounced Catiline was an orator' clearly express different thoughts. The truth-value of the sentence is what remains constant in spite of the substitution, so that should be the reference.

3 The multiple roles of sense

The sense of an expression, as we have seen, embodies its cognitive value and is solely responsible for its significance. A term that lacks a sense is therefore not a meaningful constituent of a language; however, an expression may have a sense (that is, be meaningful) and still lack reference. For example, 'the least integer' is a meaningful expression even if there is no object to which it refers. The sense of an expression determines the referent (if the expression has a referent) but, as Frege points out, there is no road back from reference to sense. Aristotle, for example, is the referent of many different terms; there is no mechanism, no procedure that would single out a sense only on the basis of what the reference is.

The sense of a sentence - the thought or proposition it expresses - determines a truth-value as reference. But truth-value typically depends on specific features of the world. Thus, given the way the world is, the sense of the sentence 'Aristotle was a philosopher' determines (we suppose) 'True' as reference. Had Aristotle never thought about philosophical questions, the sense of that sentence would determine 'False' as reference. It is the role of the

sense of a sentence to determine truth-value on whatever conditions obtain, thus the sense accounts for the truth-conditions of a sentence. Because the thought expressed by a sentence is a function of the senses of the component expressions, the sense of an expression is that expression's contribution to the truth-conditions of the sentences in which it figures.

Senses are also what speakers grasp when they understand words. Hence, language learning and linguistic competence are a matter of grasping senses. Moreover, speakers communicate linguistically with one another by grasping the same thoughts. So senses, although mentally graspable entities, should not be confused with private images or ideas. Senses are objective, so that different speakers can grasp the same senses and transmit a given thought to other speakers.

4 Compositionality and substitutivity

The Fregean theory of sense and reference espouses two basic and closely connected semantic principles: the principle of compositionality and the law of substitutivity.

The principle of compositionality states that the reference of a complex expression is a function of the references of its components, plus the way in which those components are combined (see Compositionality). Similarly, the sense of a complex expression is a function of the senses of the component expressions. Thus the reference of the sentence 'The Eiffel Tower is taller than the Empire State Building', a truth-value, is determined exclusively by the references of the meaningful components and their combination. The mode of combination is important, since a different reference would be determined if the components were combined differently, as with the sentence 'The Empire State building is taller than the Eiffel Tower'.

Since, by compositionality, the references of the parts are solely responsible for the reference of the whole, it obviously follows that coreferential terms are intersubstitutable without altering the reference of the complex expressions in which they occur. The latter is known as the law of substitutivity, which states that an expression which figures as part of another expression can be replaced with a coreferential one, and the reference of the complex will remain the same. However, the *sense* of a complex is typically altered when coreferential components are intersubstituted, if they have different senses. Thus, for example, 'Aristotle was Greek' and 'The tutor of Alexander the Great was Greek' express different thoughts but, since the latter sentence results from the exchange of coreferential terms, the reference of the two sentences is the same. (The sense of a complex remains the same if components with the same sense are intersubstituted.)

5 Non-customary contexts

The law of substitution seems to have obvious counterexamples. For example, although 'Cicero' and 'Tully' are coreferential names, the reference of sentences such as 'Mary said that Cicero was a historian' or 'John said, "Cicero was a historian"' may be altered if 'Tully' is substituted for 'Cicero'. But, according to the standard theory of sense and reference, some contexts cause shifts in the sense and reference of the expressions that occur in them. Thus the alleged failure of substitutivity is only apparent, for in the contexts in question the terms being substituted do not have their customary reference. The Fregean theory of sense and reference is essentially contextual: what an expression refers to and what its sense is depend on the context in which the expression occurs.

Consider the sentence 'The word "Cicero" contains six characters'. The reference of a word within quotation marks is not the customary referent, but rather the word itself (see Use/mention distinction and quotation). In our example, the occurrence of 'Cicero' does not refer to Cicero but to the word 'Cicero'. Clearly, the substitution of 'Tully' for 'Cicero' in that context would alter the truth-value of the sentence in question. But since 'Tully' and 'Cicero' are different words, the terms of the attempted substitution are not coreferential in that context, and therefore the observed phenomenon does not violate the principle of substitutivity.

Something similar occurs in the case of indirect quotation, such as 'Mary said that Cicero was a historian' (see Indirect discourse), and belief ascriptions, such as 'John believes that Cicero was a historian' (see Propositional attitude statements §§1-2). Here too the intersubstitution of what seem to be coreferential terms may alter the reference of the sentence. And here again, the breakdown of substitutivity is only apparent, for, according to the theory of sense and reference, expressions in contexts such as these, which Frege called 'oblique', have a non-customary referent. The non-customary referent in these cases - the oblique referent - is the customary sense

of the expression. In oblique contexts the reference of the embedded clause is the thought which that clause customarily expresses, and the reference of each of the clause's component expressions is its customary sense. So, the reference of 'Cicero' in the two sentences considered above is not Cicero but rather the sense 'Cicero' has in customary contexts such as 'Cicero was an orator', 'Cicero was a historian' and so on. In oblique contexts expressions have in turn an oblique sense, whose role is precisely to determine the oblique reference. It is an open question whether the semantic treatment of more complex embeddings requires that expressions have a higher-order sense that determines the oblique sense as reference in the context in question.

Sense perception, Indian views of

Sense perception is considered in classical Indian thought in the context of epistemological issues - in particular, perception as a source of knowledge - and of psychological and metaphysical issues, for example, the relations of sense experiences to objects, to language and to the perceiving self or subject. The Sanskrit word used most commonly in philosophical investigations of sense perception is pratyakṣa, *a compound of* prati, *'before', and* akṣa, *'eye' or any 'organ of sense'; thus it should be understood as 'being before the eyes' or 'experientially evident' as an adjective, and 'immediate experience' or 'sense experience' as a noun. The meaning 'sense perception' is normal within philosophical inquiries. But just how many sense modalities there are is not to be taken for granted. In addition to the five types of sense experience commonly identified, 'mental' perception (as of pleasures, pains and desires), apperception (awareness of awareness) and extraordinary or yogic perception are sometimes counted as* pratyakṣa.

Views about the psychology of perception or, more broadly, about perception considered as part of the world are developed in religious and soteriological literature (literature about enlightenment and liberation) predating classical philosophical discussions. In Upaniṣadic, Buddhist and Jaina texts over two millennia old, perception is painted in broad strokes within spiritual theories of self and world that promote ideas of the supreme value of a mystical experience. Sense perception is usually devalued comparatively. Later, the psychology of perception becomes very advanced and is treated in some quarters independently of soteriological teachings.

Classical Indian philosophy proper is marked by tight argumentation and self-conscious concern with evidence. The justificational value of perception is recognized from the outset, in so far as any justifiers, or knowledge sources, are admitted at all. Nāgārjuna and others challenge the epistemological projects of Nyāya and other positive approaches to knowledge, prompting deep probing of perception's epistemic role. Views about veridicality, fallibility and meaningful doubt become greatly elaborated.

What do we perceive? Throughout classical thought, sharp disagreements occur over the perceptibility of universals, relations, absences or negative facts (such as Devadatta's not being at home), parts versus wholes, and the self or awareness itself. Issues about perceptual media (such as light and ether, ākāśa, *the purported medium of sound), about occult or spiritual perceptibles and about the very existence of objects independently of consciousness are hotly debated. A Buddhist phenomenalism is polemically matched by a Mīmāṃsā and Nyāya realism on a range of concerns.*

Probably through the influence of mysticism, verbalization of experience, however simple and direct, becomes suspect in comparison with experience itself; this suspicion is evident in concerns over the value of each in presenting reality, as well as in other, sometimes rather indefinite, ways. The judgment is prevalent that what prevents a person from living in an enlightened or liberated state is thinking - verbalizing experience, calculating, planning, and so on - instead of having pure experience, perceptual and otherwise, and thus living with a 'silent mind'. This attitude emerges in treatments of sense experience, reinforcing what is perhaps a natural tendency among philosophers to find the relations of experience and language problematic. Even in the root text of Nyāya, where the influence of yoga and mysticism is not so strong, perception is said to be a cognition that is nonverbal, avyapadeśya, *although there is considerable dispute about precisely what this means. The relations between various modes of experience and the language used with respect to them remains an ongoing concern of the very latest and most complex classical Indian philosophy.*

1 Psychology of perception

This entry is concerned with classical Indian views of perception. The reflections of modern philosophers not writing in Sanskrit (such as Aurobindo Ghose, whose innovative theory has not been sufficiently explored) and academic philosophers fall outside its purview. In this section, four topics will be discussed: (a) views of perception as episodic, along with the role of psychological dispositions, called *saṃskāra*, in recognition and related cognitive processes; (b) internal perception and the internal instrument, the *manas* or 'mind'; (c) peculiarly Indian views about the operation of sense organs; and (d) the relation of perception to consciousness. With the first three topics, labelling according to school - Buddhist Yogācāra, Nyāya, Mīmāṃsā, and so on - or individual thinker is done incidentally, mainly to provide minimal historical context. Most of the positions are pan-Indian,

common across periods as well as the usual metaphysical divides, although not invariably. With the fourth topic, the stances of individual schools are discriminated, since there is much disagreement about consciousness.

In early Buddhist texts, discussion of sense perception occurs within the context of the doctrine of 'no-self', *an-ātman* (in Pāli, *anatta*), which is advanced by the Buddha apparently to facilitate disidentification with desires and other phenomenal presentations - such disidentification being considered crucial to the attainment of a mystical enlightenment. Varieties of consciousness are listed by the Buddha's interpreters in efforts to analyse the make-up of the false conglomerate commonly thought to be a self. Thus emerges a picture of streams of experience integrated into an ego that is erroneously thought to endure. Perception is considered episodic in character; a perceptual moment lasts only an instant and is followed by a distinct occurrence.

So, too, throughout the approximately two-thousand-year history of Nyāya-Vaiśeṣika and most other classical schools is found a view of perception as episodic. (The *vṛtti* notion used in Sāōkhya and Advaita Vedānta, roughly 'modification', is a change to be understood temporally.) Despite the realism of some of these philosophies, standing in sharp opposition to the most prominent Buddhist schools, there is agreement that sense experiences occur as brief episodes in a temporal series, or as an intersection of multiple series (a sense experience results from both physical and psychological factors, according to some views). Much classical Indian psychology of perception traces a complex of causal factors giving rise to particular types of awareness, with sense experiences included within the broader project.

Some of these analyses are intricate. For example, with the phenomenon of recognition (as in 'This is that Devadatta whom I saw yesterday') a perceptual factor and a memory factor are identified. The memory factor is analysed in terms of *saṃskāra*, dispositions or subconscious traces formed by a blend of past experiences and actions. Disputes centre on how the perceptual factor (expressed by 'this' in the verbalization 'This is that Devadatta') fuses with or relates to the memory dispositions. In later thought, it is well recognized that verbalizable perceptual awareness always, or almost always (or on almost all analyses), contains an admixture of concepts understood dispositionally. What some Western thinkers would call beliefs are talked about in these same terms, namely, with reference to *saṃskāra*, as is a whole range of cognitive phenomena, such as doubting, planning, expecting, and so on.

2 Psychology of perception (cont.)

Dispositions, or subconscious traces, are not the only internal factors talked about in analyses of perceptual awareness. Though there is much controversy about the nature of a cognizer or self, there is surprising consensus about an internal perceptual organ called the *manas*, commonly translated 'mind' (and here rendered as 'sense mind'), and sometimes also called *antaḥkaraṇa*, the 'internal organ'. Phenomenologically, perceptions of pleasures, pains and desires are similar to perceptions of colours, sounds, tastes, and so forth. In the latter cases, sense organs mediate, or deliver, the perceptions; thus it would appear that there must be an organ for 'internal' perceptions, too. Moreover, awarenesses originating through different sense media are synthesized - or channelled or bundled together - in such a way that a person at least seems to get a multidimensional view of the self and the world, a presentation informed by multiple senses, including the internal colourings of hedonic tone and appetitive hue. The sense mind is postulated to serve the dual function of grasping desires and the like and bundling the displays of the external senses. It is normally considered 'internal' with respect to the physical organs, as somehow nearer the seat of consciousness, but is 'external' to the self or consciousness itself. It is an instrument of awareness, but, as Sāōkhya philosophers stress, it is part of nature, not of consciousness, nor is it in itself conscious, except according to some Buddhist theorists (see Sāōkhya §2).

The nature of *manas* is filled out differently according to different schools. One important difference concerns the apparent synthesis of the deliverances of the distinct senses. In Nyāya-Vaiśeṣika, it is held that the appearance of a synthesis is an illusion comparable to the firebrand that appears to be a circle but is really a single torch whirled around rapidly. Similarly, the sense mind, which is considered atomic and capable of delivering to the self only one bit of sense-mediated information at a time, moves very rapidly among the organs and internal occurrences, giving the impression of a unified, multidimensional moment of consciousness, whereas the mosaic is really a rapid series of perceptions (see Nyāya-Vaiśeṣika §6). Again, this fuller view is by no means held by all schools, although a core theory or simple postulation of a sense mind is.

What relations hold between sense organs and the objects they grasp? According to some, all the organs come into direct contact with their objects, while others maintain that direct contact is the operative relation only with certain organs and certain objects. Most parties agree that touch operates by direct contact, also taste and smell, and most hold that the sense mind, or internal organ, works similarly too. A prominent view, though less universally espoused, is that with the seat of vision being the eyes, the visual organ itself is a ray that goes out of the body as swiftly as light (which carries it), comes into contact with objects at a distance and spreads over their illuminated surfaces. To obvious objections, proponents come up with ingenious rejoinders. Concerning hearing, there are advocates of a travelling organ, but a more prominent view is that sounds are transmitted in a special element called ether, *ākāśa*, alternatively through air, reaching the organ located in the hole in the ear. Some hold that the ether as delimited by the earhole is the sense organ.

There are issues about the relation to the grasping sense organ of objects not plausibly in direct contact with it, such as the colour and shape of a pot. We touch a pot, but not its shape, at least not directly. The visual organ may come into direct contact with the pot, but colour is not the sort of thing with which there could be direct contact, contact being a relation that holds between substances. Such issues are not pressing for Buddhist phenomenalists, since they hold that there is no essential difference between the means to awareness and awareness itself: talk of 'organs' is just a manner of speaking. But on almost all other views, considerable attention is paid to the nature of the operative relation for each type of object perceived, for example, substance, quality (and different types of quality - colours, sounds, and so on), motion, universal or absence.

Finally, the major schools take distinct positions on the question of the consciousness in perception. Yogācāra Buddhists (Buddhist phenomenalists) generally hold that every perception is conscious in itself. To postulate an additional cognizer would be otiose. Sāōkhya-Yoga propounds a strict dualism of consciousness and nature, with all perceptual apparatus as well as content regarded as part of nature. Consciousness is purely a witness, with no further, thicker relation to that which it beholds. Advaita Vedānta takes a similar view: consciousness has no relation to the modifications of the internal organ other than to be their witness. Mīmāṃsā and Nyāya-Vaiśeṣika philosophers uphold a more integrated position. In Mīmāṃsā (or, more precisely, the Mīmāṃsā of Kumārila and followers), awareness is considered a personal act, creating the quality of 'being-perceived' in an object perceived. Nyāya-Vaiśeṣika thinkers view awareness, perceptual and otherwise, as a quality or attribute of the self, a quality of brief duration, as explained above, and the result of complex causal processes. In philosophy, an awareness may be verbalized in abstraction from the person to whom it belongs, but there are no free-floating awarenesses. Nor are selves conscious except in possessing awarenesses (see Awareness in Indian thought).

3 Epistemology of perception

It is difficult to appreciate classical views on the epistemic value of perception in isolation from fuller epistemological projects where perception is identified as one of several sources of knowledge (see Knowledge, indian views of). The Sanskrit word *pratyakṣa* is normally used with an implication of veridicality; a nonveridical sense experience is not counted as *pratyakṣa*. Westerners are prone to react to this by suspecting classical Indian thinkers of missing crucial issues by presupposing too much in how they understand a term. But it is the translation 'perception' that is a little misleading. The English term 'knowledge' is normally used to imply truth of a belief. If what was considered a bit of knowledge is discovered to be in fact a false belief, then it is said that there was no knowledge in the first place, only a belief that was considered true. The same logic holds for *pratyakṣa*, substituting veridicality for truth and awareness for belief: if what was considered a perceptual awareness is discovered to be in fact nonveridical, then it is said that there was no perception in the first place, only an awareness that was considered veridical.

Little is to be gained in epistemology from semantic reflections. There is, however, a nice tie between the veridicality presupposition in the use of the term *pratyakṣa* and an important point about default justification, fallibility and the burden of proof that is central to much classical Indian epistemology. This is that doubt, like all awareness, has grounds, indeed causal grounds (as is brought out lucidly in later reflection), such as one's inability to discern a distant object that appears, say, to be perhaps a post, perhaps a person. Disagreement can be a cause for doubt, as can other sorts of cognitive tension. In such situations, we are called to look to reliable sources of information to resolve the doubt. But when the conditions for such meaningful doubt do not obtain - regarding sense experience, when conditions for doubting the reality of what we see or otherwise perceive do not obtain -

then we proceed, and have every right to proceed, assuming the experience's veridicality. Veridicality is the default assumption. And the defeasibility, or fallibility, of perceptual judgments, contributes to this right, to the default being an assumption of veridicality (along with an assumption of the truth of perceptual judgments). Were we to claim infallibility, or certitude, then the burden of proof would be on our shoulders; that is to say, the conditions for meaningful doubt would be a lot less stringent. Much of this position is worked out by members of the Nyāya school in response to epistemological scepticism advanced by the Buddhist Nāgārjuna and others. But it is also developed by the Yogācāra Buddhist Dharmakīrti and some of his followers.

Perception, *pratyakṣa*, is held to be the fundamental knowledge source, the 'eldest' (*jyeṣṭa*) source, by philosophers belonging to several distinct schools. The Cārvāka sceptic - who, with Nāgārjuna and his school and the later dialectical Advaita Vedānta of Śrīharṣa, is a common target of those with positive epistemological projects - accepts the epistemic value of perception; what the Cārvāka questions is the authority of inference and other putative knowledge sources. Nyāya itself is concerned with inference only in so far as it is to provide knowledge of the world, holding that any correct inference must have a perceptual premise. Moreover, inferential cognitions that are *prima facie* correct can be overridden by perception. This is clearly made out. Less clearly discerned, and often not at all, is the importance of inference to show the nonveridicality of a sense experience. The Dharmakīrti school, however, does propound a combination of coherentism and experiential foundationalism where considerations of coherence are viewed as potential overriders and weighted more heavily than any perceptual judgment (see Dharmakīrti; Epistemology, Indian schools of §1).

4 Perception and the world

A perceptual awareness is intentional; that is to say, it has an object or content, namely what it is *of*. But just what types of things is perception capable of revealing, and - because much of perception's epistemic value hangs on the following refinement - just what is it capable of *directly* revealing?

Yogācāra Buddhists, who are nominalists as well as phenomenalists, hold that what perception reveals is invariably unique and particular (see Nominalism, Buddhist doctrine of §§1-2). Dharmakīrti develops this stance into a pragmatism about concept-formation, justification and truth, finding inferential relations to hold only on the level of our mental fictions, not among things (or events) themselves. Indian realists, in contrast, paint a much richer picture of what we directly perceive.

To take up a highly contentious example, on the issue of how, according to the realists, an inference-underpinning pervasion, *vyāpti* (every locus of *F* as also a locus of *G*), is known, the view is that universals or class characters (natural kind characters) and relations among them are presented perceptually. To counter such objections as that from knowing the universal we should be acquainted with things strewn throughout all time, realists admit that internal factors are relevant to what in perception we are capable of verbalizing and acting upon. Of course, not everything *F* or *G* is known perceptually; what is known is *F*-hood and *G*-hood and the relation between them. A child may not be able to recognize cowhood in its generality, though the universal is available in the presence of Bessie the family cow; there is a difference between seeing cowhood and seeing it as cowhood (see §6). The realists stress their fallibilism, as well as the training often required to recognize something for what it is. Thus the relation between smokiness and fieriness, for example, may not be recognized; or we may think we perceive a connection, and a future counter-instance proves us wrong. It is wide experience (*bhūyo-darśana*) of correlations of things *F* and *G* that gives us confidence. Nevertheless, since a pervasion is a natural occurrence, one can be grasped on a single occasion. To use less technical terms, can we not know from a single witnessing that smoke is caused by fire? (Causal relations are important types of pervasion, on the realists' view, but not the only types.)

Other important ontological issues fought over with reference to direct perceptibility are relations (in particular that which the realists find between a property and a property-bearer - there is no such distinction, claim the Buddhists and, for different reasons, the Advaita Vedāntins), absences or negative facts, and the self or awareness itself (see Ontology in Indian philosophy §§1-2, 10-11; Negative facts in classical Indian philosophy). However, the focus here will be on the debates about the reality of wholes and the very existence of objects independently of consciousness; these stand close to the heart of the Buddhist-realist controversy, where so much of the best of classical Indian argument over perception is to be found.

The Buddhist tradition that the great Dharmakīrti defines, both by summarizing the arguments of his predecessors

and by setting the terms of the debate for his followers, finds a chasm between what experience directly presents and conceptual constructions. Vasubandhu (*c*.400) entertains the possibility of a universal illusion - the world as presented perceptually does not differ from the presentations of a dream - to land in a phenomenalism of event-instants. These presentations (atomic events of colour-shape, of sound, of feeling, and so on) are common to illusions and veridical experiences, common to dreaming and to waking. Wholes are mentally or imaginatively constructed (*kalpanā* is the key term: 'imagination' in classical aesthetics) out of these parts, as are enduring objects. And though important variations among Buddhists appear (whole schools are differentiated by Vasubandhu and others), generally speaking it is a mark of our spiritual ignorance that we take our constructions to be real. The only true difference between dreaming and waking is that between individual and mass delusion, between an imaginative construction or projection due to individual karma (dispositions built from past actions) and projections due to common karma. (Dharmakīrti says the nature of our constructions are due to our desires.)

With this view as background, Buddhists find an easy target in the realist view of wholes (such as in Nyāya), for the claim is not only that a whole, such as a tree, is in itself a reality other than the totality of its parts, but that when we perceive a tree we directly perceive the whole. (How ridiculous! Are the roots then directly perceived?) The deep issue is what counts as basic evidence. The Buddhists maintain that it is the atomic-event presentations common to illusions and veridical experiences. Nyāya philosophers counter that we see wholes, and they do not mean to use a different sense of 'see': we directly perceive wholes; perception of wholes is the basic evidence.

5 Perception and the world (cont.)

The *Nyāyasūtra* (2.1.33-5) presents two nonphenomenological lines of argument to shore up the position (phenomenological appeals, at this point, would beg the question). The first is that the view that we see a part presupposes that we see a whole - a part of what? Moreover, if we see only parts, then presuming a part is a macro object, it must have parts, and so *it* turns out not to be seen. Or if it is partless, it is so minute as to be imperceptible (some Buddhists do admit that, strictly speaking, the event-instants are not consciously perceived). Thus if we cannot see wholes, we can see nothing at all. The second line of argument is that only by assuming a whole can we explain holding and pulling. Only wholes, not parts (at least of some things), can be moved about. The realists also purport to have an answer to the Buddhist argument about a common core to veridical and illusory experiences in their theory of nonveridical awareness (see Error and illusion, Indian conceptions of §§1-2). Concerning objects' independence of consciousness, they continually invoke considerations of intersubjectivity and then, in later periods, supplement such arguments with an appeal to parsimony (*lāghavatva*, theoretic 'lightness') as the decisive advantage of their position.

The Buddhists, for their part, seem driven by an idealism that is tied to an understanding of what makes *nirvāṇa* experience possible: if objects were independent of experience, there could be no enlightenment, no consciousness of a single interdependent reality as is taught by the Buddha. On the other hand, Dharmakīrti achieves a pragmatism built on a more moderate view of a fundamental reality, indeed a sophisticated scepticism. That is, what is fundamentally real may be problematic, but as far as our everyday activities are concerned, all we need take to be real is what is capable of satisfying our desires. Our perceptions are to be understood as revealing things that are in this way causally efficient, so long as they cohere with other bits of knowledge.

Backing away from extreme idealist statements would seem an advantage polemically. But the realists get the last word in the debate with the Buddhists, for Nyāya and Mīmāṃsā as schools outlast Buddhist philosophy in India by several centuries. In the later period, many Buddhist arguments and positions are, however, taken over by Advaita Vedāntins.

Concerning what some call yoga-born perception and the spiritual matters putatively revealed by it, many philosophers addressing the topic do not seem themselves to have been yogins, and the views presented involve only minor extensions of common positions in the psychology of perception. Through yoga and the accumulation of religious merit, the organs of perception are modified, particularly the sense mind (*manas*), such that spiritual matters, or things subtle, remote or normally hidden, are directly perceived. Such speculation is supposed to show how extraordinary perception is possible; given the possibility, an epistemic parallelism between ordinary and extraordinary perception is upheld.

6 Perception and language

A range of views about the relation, or multiple relations, between perception and language-mediated thought - running alongside it, unfolding concepts implicit in it, perverting it, abstracting from it, referring to things revealed by it - occurs in classical Indian schools. We shall begin with a quick look at the panoply of positions and views in an abbreviated and general form.

Bhartṛhari, an astute grammarian and psychologist of the fifth century, appears to embrace a metaphysics where all awareness would be manifestation of a primordial Word, with several gradations or levels of ideas/language. He more than anyone else is responsible for provoking classical philosophers to suspect that there is no non-language-mediated consciousness. But Patañjali too, the author of the *Yogasūtra* (*c.*400), promotes the view that short of the highest mystic trance, the ultimate liberation and enlightenment, all mentality is shot through with seeds of concepts and speech. As mentioned, it is in Buddhist traditions that we find views of perception as utterly foreign to language: the mind-stream runs alongside perception or alters it so that it is no longer in its language- and concept-free native state. The realists are influenced on this score by their opponents, and the *Nyāyasūtra* pronounces perception to be nonverbal. Nevertheless, as a knowledge source, perception is taken not only to reveal things but to warrant judgments about the things that it reveals. Dharmakīrti himself, though in a hedged and qualified manner, accords perception a similar role. Moreover, it seems all the later philosophers come to recognize that it is only speech behaviour, *vyavahāra*, reflecting experience (presumably), that is of any use in philosophical debate. Universally, the need is felt to be able to account for, or at least take into consideration, common perceptual judgments and a wide range of speech acts.

The fourteenth-century Navya-Nyāya (‘New Logic’) philosopher Gaōgeśa (§2) accepts as a first principle of verbalizable awareness - that is, awareness reflected in speech behaviour and useful in our lives - that whatever an awareness is of, namely a qualificandum, is cognized as something or other: anything *x* is known as some predicate , a qualifier. But in order to be able to recognize and talk about a qualificandum as , we have to have a prior awareness of ; otherwise, we would not be able to see or talk about the object as . Thus it would seem that has to be cognized as something or other, and an infinite regress of qualification looms. In other words, Gaōgeśa views even the simplest verbalizable awareness as having an object that is ontologically complex. Such an awareness is *viśiṣṭa*, ‘qualified’, by which he means that a qualificandum is cognized through a qualifier. Thus in order to avoid an infinite regress of qualification (the qualifier$_1$ of qualificandum$_1$ as itself a qualificandum, qualificandum$_2$, to be known through another qualifier, qualifier$_2$, *ad infinitum*), Gaōgeśa posits indeterminate awareness, where qualifiers are directly cognized. To cognize Bessie as a cow presupposes acquaintance with cowhood, that is, awareness of the ground for application of the term ‘cow’. Thus there appears a danger of an infinite regress: *how* is the qualifier cognized? And so qualifiers such as cowhood must be directly available - in what Gaōgeśa calls, borrowing a Buddhist term, indeterminate (or non-propositional) awareness, which may be considered as a first phase of the causal process that results in a determinate, verbalizable awareness. Thus, in sum, there are two phases of sense perception according to New Logic, an indeterminate one where qualifiers are directly grasped in an immediate and nonverbalizable way, followed by determinate perception, which is propositional in content and verbalizable in terms that capture a fact perceived (that is, given that the perception is veridical).

Seeing cowhood and seeing it *as* cowhood are not the same. The ground for recognizing the universal would be ‘cowhoodness’, which is, according to Gaōgeśa’s followers, not an additional real. But here we threaten to pass into ontological and logical matters that occupy the latest of the New Logicians, and to exceed the confines of our charge.

Sense-data

A philosophical theory of perception must accommodate this obvious fact: when someone perceives, or seems to perceive something, how things appear may differ from how they are. A circular coin tilted will look elliptical. A stick partially immersed in water will look bent. Noting that appearance and reality do not always coincide, some philosophers have given the following account of the contrast between the two. Suppose someone seems to see a book with a red cover. Whether or not there is any book to be seen, the individual seeming to see the red book will be aware of something red. What they are aware of is called a sense-datum. According to a sense-datum theory, any perceptual experience involves awareness of a sense-datum whether or not it is an experience of a physical object.

Some philosophers link a sense-datum theory with certain views about knowledge. According to foundationalists all knowledge of the external world must rest on a foundation of beliefs that are beyond doubt. We can always be mistaken about what physical objects are like. On the other hand, we cannot be mistaken about what sense-data are like. So, all knowledge about the external world rests on beliefs about sense-data. In this way a sense-datum theory is supposed to do double duty in contributing towards an account of perception, and an account of knowledge based on perception.

1 Sense-datum theories

The term 'sense-datum' was coined early this century by Bertrand Russell. However, sense-datum accounts of perception go back much further. When Locke, Berkeley and Hume refer to ideas of sense, sensible qualities or impressions of sense frequently they appear to be referring to what we would now call sense-data.

In this century early advocates of sense-data intended the term 'sense-datum' to be neutral. Philosophers adopting opposed views about perception were supposed to be able to agree that any case of perceiving involves an awareness of sense-data, even if they then disagreed about what sense-data actually are and how they relate to the physical. A sense-datum may be a physical object, or it may be non-physical; it may exist only when perceived, or exist unperceived; it may be an event, or belong to some other category; it may be perceivable by only one individual, or more than one. But, however these issues are resolved, it is said to be undeniable that I am aware of a circular gold sense-datum. In this way sense-data, understood neutrally, are supposed to provide the foundation on which to erect competing theories of perception.

Sense-data are supposed to explain how perceptual experiences can fail to match reality. The book appears red even though it is some other colour. How can this be? Because the individual looking at it is aware of a red sense-datum. The coin appears elliptical even though it is circular: the individual looking at it is aware of an elliptical sense-datum. Sense-data, it is said, are what one is aware of in virtue of having perceptual experiences.

Call a perceptual experience veridical just in case in having it one seems to perceive an object with those qualities. I have a perceptual experience as of seeing a grey surface. My experience is veridical because I am seeing a grey surface. Now consider someone who is having a non-veridical experience. Consider the alcoholic who has an experience as of seeing a pink rat. According to the sense-datum theorist, even if not seeing a pink rat, the alcoholic is having an experience as of seeing something pink because they are aware of something pink. The alcoholic is aware of a pink sense-datum. Hence, sense-datum theorists are committed to:

(i) Every perceptual experience involves an awareness of a sense-datum.

G.E. Moore once toyed with the idea that a sense-datum can appear to have characteristics it lacks. However, allowing that sense-data may not be as they appear undermines a central role that sense-data are supposed to play in perception. Sense-data are appealed to, in part, to explain how the apparent characteristics of a physical object can differ from its actual characteristics. That explanation would be undermined if the apparent characteristics of a sense-datum could, likewise, differ from its actual characteristics. For that reason, sense-datum theorists are also committed to:

(ii) At least for a certain range of characteristics, it is impossible for a sense-datum to appear to have a characteristic that it lacks.

A physical object can appear red or round without being red or round. A sense-datum cannot appear red or round without being red or round.

Apart from (i) and (ii) other features have commonly been attributed to sense-data. Some say that sense-data are private: it is metaphysically impossible for more than one individual to be aware of the same sense-datum. Some say that sense-data are transient: it is metaphysically impossible for one sense-datum to be perceived discontinuously. Some say that sense-data are self intimating: for a restricted range of characteristics, a sense-datum must appear to have any characteristic that it has. These features, privacy, transience, mind dependence, and self intimation are optional in the following sense. Lacking any of the features in question will not disqualify sense-data from playing a role in the theory of perception.

A.J. Ayer proposed an unorthodox interpretation of sense-datum theories. His interpretation has become known as the alternative language view. Ayer accepts that a sense-datum theory is not open to empirical confirmation or disconfirmation. Since that is so, he is reluctant to treat a sense-datum theory as a theory about the existence of a special class of entities called sense-data. Instead, he views advocacy of a sense-datum theory as a recommendation to use language in a particular way. Consider again the coin that first appears circular to Jayne, then elliptical. She could describe the perceptual facts by saying that she was aware first of a circular sense-datum, then of an elliptical sense-datum. Alternatively, she could describe them by saying that the coin she perceived changes from being circular to being elliptical. Which description is correct? In Ayer’s view neither. Which description Jayne selects, the sense-datum description or the one that has implausible implications about the stability of objects, is simply a matter of convenience.

2 Arguments for the existence of sense-data

I will use ’sense-datum’ to refer to things that, at least, satisfy (i) and (ii). What reason is there to think that there are sense-data? Many arguments have been offered, but all depend on contestable assumptions that are rarely defended in the literature.

The perception of parts argument One cannot perceive an object unless one perceived every part of it. Whenever one looks at a physical object one does not perceive every part of it. So, whenever one looks at a physical object, one perceived something distinct from it: a sense-datum. This argument is only as plausible as its first premise, which to many people does not seem plausible at all.

The certainty argument Suppose one takes oneself to see a tomato. One cannot be certain that one is seeing a tomato. Nevertheless, one can be certain that one is seeing something that looks red, round and bulgy. So, the red-, round- and bulgy-looking thing one is certain of seeing is not the tomato, or any part of it. It is a sense-datum.

This argument depends on three assumptions. First, it is assumed that, in the case of seeing the tomato, one cannot be certain that a tomato exists. Second, it is assumed that one can be certain that a red-, round-, and bulgy-looking thing exists. Finally, it is assumed that if I am certain that a red-, round- bulgy-looking thing exists but uncertain that a tomato exists, then the red-, round- bulgy-looking thing is not the tomato. In general, however, it does not follow from someone being certain that a exists, and uncertain that b exists, that a is not identical with b.

The causal argument Perception involves a causal chain extending from a physical object to a perceiver. What is really perceived is only what is at the end point of the causal chain: a sense-datum. This argument depends upon the unwarranted assumption that only the end point of a causal process which enables one to see something can be perceived.

The time lag argument When someone perceives a very distant object, for example a star, light takes a long time to reach their perceptual apparatus. Because it does so, the star may have ceased to exist by the time the silvery speck taken to be the star is perceived. Hence, the silvery speck is not identical with the star. It is a sense-datum. This argument depends upon the assumption that nothing can be perceived unless it exists at the same time that it is perceived.

The argument from analysis Any case of veridical or non-veridical perception involves having a perceptual experience and, it is agreed, having a perceptual experience is best analysed as awareness of an object. The object in question is a sense-datum.

Why should we think that having a perceptual experience is best analysed as awareness of an object? Suppose someone sees a red after-image against a white wall. Surely that individual is aware of *something* red which is both an after-image and sense-datum. After all, there seems to be something, an after-image, obscuring part of the wall in much the way that a physical red patch would do.

Or consider the following three cases. In the first someone is looking at some yellow curtains through blue tinted spectacles. In the second someone is looking at the same curtains without anything impeding or distorting that person's vision. In the third someone is hallucinating a yellow surface without seeing any physical surface with that colour. The second and third cases share something is common which they do not share in common with the first. In the first someone in aware of some yellow curtains without being aware of their colour. In the second and third someone is aware of the colour, yellow, which is in fact the colour of the curtains. How can someone be aware of the colour of the curtains in the third case, unless they are aware of *something*, a sense-datum, with that colour?

The problem with the argument from analysis is that it relies on the sense-datum theorist's analysis of having a perceptual experience being superior to any other. However, alternative analyses have been defended in the literature. One implies that perceptual experiences invariably have objects, but treats the objects of perceptual experiences as intentional (see Intentionality). Another treats perceptual experiences as dispositions to believe (see Perception). According to a third, the adverbial analysis (see Mental states, adverbial theory of), perceptual experiences need not have objects. For example, if it is said that someone is experiencing a red after-image, the expression 'red' is used to specify how the person is experiencing rather than a quality of an experienced object.

Frank Jackson has recently argued for the superiority of a sense-datum analysis over these competitors. For example, he argues that an analysis of perception in terms of sense-data can, in contrast to an adverbial analysis, explain the validity of certain incontestably valid arguments concerning appearances.

3 The relationship between sense-data and physical objects

Direct realists (see Perception §4) hold that in perception one is often directly or immediately aware of the surfaces of physical objects. The famous argument from illusion has been used to refute direct realism and is said to show that sense-data are never identical with the surfaces of physical objects. Suppose Jayne looks at the same surface of a coin over an interval of time during which it is rotated. At first the coin looks circular. Later it looks elliptical. Since the coin does not change shape, the elliptical items that Jayne is later aware of are, presumably, not identical with the surface of the coin. As the coin rotates Jayne is aware of a series of things. The first member is circular, and the last elliptical. It is implausible to maintain that the first member of the series is a physical surface, and the later elliptical members things of a totally different kind. We should allow that, as the coin rotates, all of the differently shaped things Jayne perceives are sense-data. In general, one immediately perceives only sense-data whenever one perceives a physical object.

What is the relationship between immediately perceived sense-data and physical objects? According to representative realists, sense-data interpose between the physical world and the perceiver's awareness of it and represent physical objects to the perceiver in virtue of standing in an appropriate relation, usually though of as causal, to those objects (see Perception §2). According to one version of idealism physical objects are collections of mind dependent sense-data (see Idealism §2). According to one version of phenomenalism statements about physical objects are analyzable as statements about the sense-data one would have if one were suitably located (see Phenomenalism).

It should be noted that, of the above views about the relationship between sense-data and physical objects, only representative realism requires reference to sense-data for its formulation. There are versions of idealism and phenomenalism that make no mention of sense-data. On the other hand, any version of representative realism will have to incorporate reference to sense-data.

4 Objections to sense-data

A multitude of objections have been raised against sense-data, to which, naturally, sense-datum theorists have replies.

The individuation objection. When I see something am I aware of a single visual sense-datum, or a number of sense-data? How can I tell whether I am aware of the same sense-data at different times? These questions, it is said, are unanswerable since we lack criteria for the identity of sense-data.

This objection presupposes that lack of precise criteria for individuating sense-data constitutes an objection to their existence. However, we lack precise criteria for individuating many things we believe in such as persons or ships.

The private language objection. If sense-data exist, we can refer to them. Sense-data are essentially private objects. Hence, sense-data can only be referred to using a private language. However, it is agreed, private languages are impossible (see Private Language Argument). This objection presupposes that sense-data must be private, and, more dubiously, that one cannot refer to private objects using a public language.

The intelligibility objection. For a sense-datum theory to be intelligible certain distinctions have to be grasped such as the distinction between sense-data and material objects, or the distinction between direct and indirect perception. However, these distinctions are not really intelligible when they are applied as the sense-datum theorist wishes to apply them. For example, it only makes sense to say that something is directly perceived if it is possible to indirectly perceive it. According to the sense-datum theorist, a sense-datum can only ever be directly perceived.

This objection appears to rest on much disputed theses about the nature of language, and in particular on the thesis that an expression only meaningfully applies to something if there could be a thing of the same kind to which the expression does not apply.

The indeterminacy objection. If something exists it must be determinate in the sense that, for any property, it either has or lacks that property. But sense-data are not determinate. I see a hen which appears to have a certain number of speckles. Despite that, for any number of speckles, the hen does not appear to have that number of speckles. So, the sense-datum I am aware of when I see the hen is speckled without having any particular number of speckles. It is indeterminate.

This objection assumes that, not only must a sense-datum be as it appears, but a sense-datum must appear in every respect as it is. Unless this is so, the sense-datum of the speckled hen may, like the hen itself, have a determinate number of speckles without appearing to have that number of speckles.

Sergeant, John (1623-1704)

John Sergeant was the last of the Blackloists - the faction of English Catholics who followed the thought of Thomas White in the middle decades of the seventeenth century. As such his major philosophical concern was with a refutation of scepticism, and to that end he adopted a synthesis of Aristotelianism and aspects of the new philosophy. Sergeant is now best remembered as the main Catholic protagonist in the theological 'rule of faith' debates, when he engaged with such eminent Anglicans as Tillotson and Stillingfleet to argue the cause of religious certainty, attainable only through Catholic tradition. Turning later to the need for certainty in philosophy and science, he formulated his own 'solid philosophy': within an essentially Aristotelian framework, he incorporated aspects of the new thought that had been earlier adopted by Thomas White and Kenelm Digby.

John Sergeant's conversion to Catholicism took place after his graduation from St John's College, Cambridge, in 1643. Having then spent some twelve years at the English Catholic College at Lisbon, he returned to England in 1655, and acted as Secretary to the English Catholic Chapter during the height of its Blackloist influence, until 1667. His reputation as a disciple of the discredited Thomas White, and his own incrimination in the 'Popish Plot', have resulted in long historical neglect. He remains, however, not only of theological importance, but also of considerable philosophical interest. In particular, his two late works, *The Method to Science* (1696) and *Solid Philosophy Asserted* (1697), are significant as purporting to provide the means for a last-ditch defence against encroaching scepticism.

Sergeant is essentially a late Aristotelian, and he specifically opposes such proponents of new thought as Descartes and Locke. The trouble with these 'ideists' is that they reduce our ideas or conceptions to mere representations or similitudes. We are then left without criteria for distinguishing which similitudes are true and which false, and we are reduced to predicating reality only of the contents of our own minds; and this is to be reduced to scepticism. The remedy is to ground one's knowledge in empiricism: simple notions are to be assumed, which leave bodies and enter through our sense-organs into our minds. Such notions are actual physical entities, actual parts of the original body; so that our apprehension of them is incontrovertible, inasmuch as they do not *represent* the external object, but actually *are* a part of that object.

With notions thus conceived as sense-data, with respect to which there is no room for misunderstanding, some solid foundation has been laid for the acquisition of certain knowledge. Admittedly, there is room for subsequent misunderstanding, as cognition consists in linking together those notions in an orderly way, such that there is 'conformity of the understanding to the thing'; but, by taking care to avoid misunderstanding and linguistic ambiguities, we may proceed to certain knowledge. Whereas 'ideists' ground their philosophical work on abstractions which have a dubious relationship with the object they purport to represent, Sergeant claims that his own empirically-based philosophy is founded on direct knowledge of 'things themselves'. From that secure starting-point, further knowledge can be attained by means of traditional Aristotelian syllogistic reasoning.

Sergeant's position, then, is derived in part from Aristotle, for whom direct apprehension of external objects gave clear though necessarily limited knowledge, and for whom syllogistic reasoning provided the subsequent path to truth. But Sergeant is indebted also to his Blackloist friends Thomas White and Kenelm Digby, who had earlier adopted a 'mechanical' theory of perception, in terms of which material particles were directly received by our sense-organs, having emanated from bodies in an imperceptible but material 'effluvium'.

Sergeant's philosophy is ultimately underpinned by his theology. In this his prime concern is with asserting the necessity of Catholic tradition to ensure certainty, but he also reveals the religious foundations of his assumed philosophical certainties. Thus, the self-evident propositions on which his logic is to be based are themselves derived from a deity who justifies the most supremely self-evident proposition that 'self-existence is self-existence'. Without God's self-existence, the whole of logic itself might be suspect; and without belief in a God who created an orderly nature, our assumption of a correlation between our logical theories and the natural world would be further undermined. 'An atheist can have no perfectly certain knowledge or evidence of anything'; and such a sceptical outcome has by all means to be resisted.

Set theory

In the late nineteenth century, Georg Cantor created mathematical theories, first of sets or aggregates of real numbers (or linear points), and later of sets or aggregates of arbitrary elements. The relationship of element a to set A is written $a \in A$*; it is to be distinguished from the relationship of subset B to set A, which holds if every element of B is also an element of A, and which is written* $B \subseteq A$*. Cantor is most famous for his theory of transfinite cardinals, or numbers of elements in infinite sets. A subset of an infinite set may have the same number of elements as the set itself, and Cantor proved that the sets of natural and rational numbers have the same number of elements, which he called* $\aleph_0$*; also that the sets of real and complex numbers have the same number of elements, which he called c. Cantor proved* $\aleph_0$ *to be less than c. He conjectured that no set has a number of elements strictly between these two.*

In the early twentieth century, in response to criticism of set theory, Ernst Zermelo undertook its axiomatization; and, with amendments by Abraham Fraenkel, his have been the accepted axioms ever since. These axioms help distinguish the notion of a set, which is too basic to admit of informative definition, from other notions of a one made up of many that have been considered in logic and philosophy. Properties having exactly the same particulars as instances need not be identical, whereas sets having exactly the same elements are identical by the axiom of extensionality. Hence for any condition Φ *there is at most one set* $\{x|\Phi(x)\}$ *whose elements are all and only those x such that* $\Phi(x)$ *holds, and* $\{x|\Phi(x)\} = \{x|\Psi(x)\}$ *if and only if conditions* Φ *and* Ψ *hold of exactly the same x. It cannot consistently be assumed that* $\{x|\Phi(x)\}$ *exists for every condition* Φ*. Inversely, the existence of a set is not assumed to depend on the possibility of defining it by some condition* Φ *as* $\{x|\Phi(x)\}$*.*

One set x_0 *may be an element of another set* x_1 *which is an element of* x_2 *and so on,* $x_0 \in x_1 \in x_2 \in \ldots$*, but the reverse situation,* $\ldots \in y_2 \in y_1 \in y_0$*, may not occur, by the axiom of foundation. It follows that no set is an element of itself and that there can be no universal set* $y = \{x|x = x\}$*. Whereas a part of a part of a whole is a part of that whole, an element of an element of a set need not be an element of that set.*

Modern mathematics has been greatly influenced by set theory, and philosophies rejecting the latter must therefore reject much of the former. Many set-theoretic notations and terminologies are encountered even outside mathematics, as in parts of philosophy:

pair	$\{a,b\}$	$\{x \mid x = a \text{ or } x = b\}$
singleton	$\{a\}$	$\{x \mid x = a\}$
empty set	$\emptyset$	$\{x \mid x \neq x\}$
union	$\cup X$	$\{a \mid a \in A \text{ for some } A \in X\}$
binary union	$A \cup B$	$\{a \mid a \in A \text{ or } a \in B\}$
intersection	$\cap X$	$\{a \mid a \in A \text{ for all } A \in X\}$
binary intersection	$A \cap B$	$\{a \mid a \in A \text{ and } a \in B\}$
difference	$A - B$	$\{a \mid a \in A \text{ and not } a \in B\}$
complement	$A - B$	
power set	$\wp(A)$	$\{B \mid B \subseteq A\}$

(In contexts where only subsets of A are being considered, $A - B$ *may be written* $-B$ *and called the complement of B.)*

While the accepted axioms suffice as a basis for the development not only of set theory itself, but of modern mathematics generally, they leave some questions about transfinite cardinals unanswered. The status of such questions remains a topic of logical research and philosophical controversy.

1 The axioms of set theory

The axiom of *extensionality* states that sets having exactly the same elements are identical. The axiom of *foundation* states that there is no infinite descending sequence of sets $\ldots \in x_2 \in x_1 \in x_0$. The basic

Zermelo-Fraenkel axioms (ZF; see Zermelo 1908) consist of the axioms of extensionality and foundation and existence axioms stated below. The accepted axioms ZFC consist of ZF plus the axiom of choice (AC): given a partition or set *x* of sets that are non-empty (each has at least one element) and disjoint (no two have a common element), there exists a choice set *y* having exactly one element in common with each element of *x*.

The intuition behind the axioms is that sets lie in a hierarchy of levels (see Set theory, different systems of §5), and when $x \in y$, then *x* lies below and *y*, above. At the lowest level there is just $\emptyset$ (though a variant of the standard notion allows at this level 'individuals' or items that have no elements and are not sets but may be elements of sets of any level). There is no highest level (though a variant allows a top level of 'classes' or items that may have sets of any level as elements but are not themselves sets nor elements of anything). If set *x* lies at one level then the 'successor' of *x*, $x^{\#} = x \cup \{x\}$ lies at the next higher level. The levels continue into the infinite, so that above $\emptyset$, $\emptyset^{\#} = \{\emptyset\}$, $\emptyset^{\#\#} = \{\emptyset, \{\emptyset\}\}, \ldots$ lies the set $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}, \ldots\}$, whose existence is asserted by the axiom of *infinity*. The hierarchy is supposed to be as 'tall' and as 'wide' as possible, an intuition (only) partly expressed by the remaining existence axioms. These consist of axioms asserting the existence of the pair, union and power sets, along with infinitely many further axioms of each of two kinds. First, for any condition $\Phi(x)$ there is an axiom asserting that, for any set *u*, *separation* from *u* of those elements *x* for which $\Phi(x)$ holds forms a set:

$$\{x \in u | \Phi(x)\} = \{x | x \in u \text{ and } \Phi(x)\}$$

Second, for any binary condition Ψ there is an axiom asserting that if for every *x* there is a unique $y = \psi(x)$ such that $\Psi(x, y)$ holds, then for any set *u*, *replacement* of each element *x* of *u* by $\psi(x)$ forms a set:

$$\{\psi(x) | x \in u\} = \{y | \Psi(x, y) \text{ for some } x \in u\}$$

(In a rigorous formalization, the vague, intuitive notion of 'condition' would be explained in terms of a precise, logical notion of a 'formula' of a symbolic language.)

To develop mathematics on the basis of these axioms, for each system of numbers, points or other mathematical objects, a system of set-theoretic objects must be specified to serve as substitutes. Usually the system of set-theoretic substitutes is easy to specify intuitively, in terms of the relationship of the substitutes to the original objects, but it may be less easy to define formally, in terms taken only from the language of set theory. Set-theoretic counterparts to the basic operations on the original objects must also be defined in the language of set theory, and the counterparts of the basic laws for these operations deduced from the axioms of set theory. When this is done, the set-theoretic substitutes are thereafter called by the name of the mathematical objects in question, which are said to have been 'identified with' their set-theoretic substitutes.

No more can be done here than to describe intuitively for the natural, integral, rational, real and complex numbers the related sets with which these numbers are identified. First, each natural number $n \in \mathbb{N}$ is identified with the *set* of natural numbers less than *n*, so that $0 = \emptyset$, $1 = \{0\} = \{\emptyset\}$, $2 = \{0, 1\} = \{\emptyset, \{\emptyset\}\}$, and so on; and $\mathbb{N}$ itself with the set whose existence is asserted by the axiom of infinity (above). For other kinds of numbers, one needs the identification of the ordered pair (a, b) of a, b with the set $\{\{a\}, \{a, b\}\}$, which allows one to define

$$\begin{aligned}
A \oplus B &= \{(0, a) | a \in A\} \cup \{(1, b) | b \in B\} \\
A \otimes B &= \{(a, b) | a \in A \text{ and } b \in B\} \\
B^A &= \{F \subseteq A \otimes B | \text{ for all } a \in A \text{ there is} \\
&\qquad \text{a unique } b \in B \text{ with } (a, b) \in F\} \\
\mathrm{dom}(F) &= \{a | (a, b) \in F \text{ for some } b\} \\
\mathrm{ran}(F) &= \{b | (a, b) \in F \text{ for some } a\} \\
F \lceil C &= \{(a, b) \in F | a \in C\} \\
F[C] &= \{b | (a, b) \in F \text{ for some } a \in C\} \\
F^{-1}[C] &= \{a | (a, b) \in F \text{ for some } a \in C\}
\end{aligned}$$

and to define a relation on *A* or a function from *A* to *B* to be a subset of $A \otimes A$ or an element of B^A, respectively, so that, intuitively, a relation *R* or function *F* is identified with the set of pairs (a, b) such that *aRb* or $F(a) = b$. (Then the notions dom(*F*), ran(*F*), $F \lceil C$, $F[C]$ and $F^{-1}[C]$ agree with certain customary notions from

mathematical analysis, where they are called the ‘domain’ (or set of arguments), ‘range’ (or set of values), ‘restriction’, ‘image’ and ‘pre-image’.)

Now an integer *w* can be identified with the set of pairs of naturals whose difference is *w*; a rational *x* with the set of pairs of integers whose quotient is *x*; a real *y* with the set of rationals $x < y$ or, alternatively, with the set of functions *f* from naturals to rationals such that $f(x)$ for larger and larger *x* gives a better and better approximation to *y*; and a complex *z* with the ordered pair of its real and imaginary parts (each a real number). Ultimately any hypothesis that can be stated in conventional mathematical language can be stated in the language of set theory, and any theorem provable by conventional mathematical methods can be proved from the axioms ZF, with AC, or one of its many known implications, such as ‘dependent choice’ (DC), being needed in certain branches of higher mathematics. (DC asserts that if *R* is a relation on *A* such that for every $a \in A$ there exists at least one $b \in A$ with *aRb,* then there exists a function *F* from $\mathbb{N}$ to *A* with $F(n)RF(n+1)$ for all $n \in \mathbb{N}$.)

2 Ordinal numbers and ordinal arithmetic

One equivalent of AC that is widely used in mathematics is called ‘Zorn’s lemma’. A ‘partial order’ on a set *A* is a relation *R* such that for all $a, b, c \in A$ one has

aRa	(reflexivity)
If aRb and bRa then $a = b$	(antisymmetry)
If aRb and bRc then aRc	(transitivity).

R is an ‘order’ (also called a ‘total order’ or ‘linear order’) on a given $C \subseteq A$ if for any $a, b \in C$ either *aRb* or *bRa* (dichotomy). If *R* is an order on (all of) *A*, one often writes ‘ $\leq$’ (‘less than or equal to’) for *R*, and uses the common notations and terminology ‘ $<$’, ‘ $\geq$’, ‘ $>$’ and so on in the usual way. Even if *R* is only a partial order on *A*, one can use such notions as that of an ‘upper bound’ *d* for $C \subseteq A$ (*cRd* for all $c \in C$), but one must be careful to distinguish the notion of a ‘maximum’ element ($d \in C$ such that *cRd* for all $c \in C$) from that of a ‘maximal’ element ($d \in C$ such that, for any $c \in C$, *dRc* implies $c = d$), and similarly for ‘minimum’ and ‘minimal’.

Zorn’s lemma states that if *R* is a partial order on *A* and every $C \subseteq A$ on which *R* is a total order has an upper bound, then *A* has a maximal element.

The equivalent of AC most widely used in set theory is the ‘well-ordering’ principle, which asserts that every set can be well-ordered. A ‘well-order’ on a set *A* is a total order which also has the property that every non-empty subset of *A* has a minimum element (groundedness).

Cantor introduced two kinds of transfinite numbers: cardinal and ordinal. The cardinal (number) of a set is concerned only with the ‘size’ of the set; an ordinal also with the relationship of its elements. To define an ordinal, we must first define isomorphism. A function $F: A \rightarrow B$ is a ‘bijection’ (that is, a one-one, onto mapping) if for every $b \in B$ there is exactly one $a \in A$ with $F(a) = b$. Given (total) orders *R, S* on sets *A, B,* a function $F: A \rightarrow B$ ‘preserves order’ if for any $a, a' \in A$ one has aRa' if and only if $F(a)SF(a')$. An ‘isomorphism’ is a bijection that preserves order. The ‘order type’ of an order *R* is written $|R|$. $|R| = |S|$ if there is an isomorphism from *R* to *S*, and $|R| \leq |S|$ if there is an isomorphism from *R* either to *S* or to an initial sub-order of *S*, $S_b = S \lceil B_b$. An ‘initial sub-order’ is the order on the ‘initial subset’ $B_b = \{b' \in B | b'Sb \text{ and } b' \neq b\}$, for some $b \in B$. An ‘ordinal’ is the order type of a well-order.

If ρ is the ordinal of a well-order on a set of cardinality α, then ρ will also be said to be of cardinality α. By the well-ordering principle, every cardinal is that of some ordinal; and it follows from the definitions that if ordinals ρ, $\mathbf{\Sigma}$ are of cardinality α, β and $\rho \leq \mathbf{\Sigma}$, then $\alpha \leq \beta$. (To avoid confusion arising from the traditional use of the same notations for both cardinal and ordinal numbers, we will use the letters α, β, γ for cardinals, and ρ, $\mathbf{\Sigma}$, τ for ordinals.)

Cantor proved that the order on the ordinals (defined above) is a well-order. Hence there is a least or zero ordinal. For every ordinal ρ there exists a greater ordinal and hence, again by the definition of a well-order, a *least* greater ordinal, called its successor, $\rho^{\#}$. For every set *T* of ordinals there is an ordinal greater than or equal to each of its elements, hence a least such ordinal, called its ‘supremum’, $\sup T$. (Note this implies that there can be no set of all ordinals.) A ‘limit’ (ordinal) is one that is neither zero nor a successor.

The ordinals 0, $1 = 0^{\#}$, $2 = 1^{\#}, \ldots$ less than the least limit are called 'finite', and the least limit $\sup\{0, 1, 2, \ldots\}$, the ordinal of the natural order on the natural numbers, is called ω_0 or simply ω. It follows from the definitions that if $\mathbf{\Sigma}$ is the ordinal of a well-order *S* on a set *B*, then there is an isomorphism *F* from *S* to the order on the set $\{\rho | \rho < \mathbf{\Sigma}\}$ of ordinals less than $\mathbf{\Sigma}$ (namely, $F(b) = |S_b|$ for $b \in B$). It is now customary to identify the ordinal $\mathbf{\Sigma}$ with this set of lesser ordinals (generalizing what was done in the case of finite ordinals - natural numbers - in §1). With this identification, it is easy to describe explicitly $\rho^{\#}$ and $\sup T$: they are just $\rho \cup \{\rho\}$ and $\cup T$, respectively. Thus

$$\omega^{\#} = \{0, 1, 2, \ldots, \omega\}$$
$$\omega^{\#\#} = \{0, 1, 2, \ldots, \omega, \omega^{\#}\}$$

and so on; and the next limit is

$$\omega^{\dagger} = \{0, 1, 2, \ldots, \omega, \omega^{\#}, \omega^{\#\#}, \ldots\}.$$

Addition and multiplication for order types can be defined as follows. Given linear orders *R*, *S* on sets *A*, *B*, one defines orders $R \oplus S$, $R \otimes S$ on $A \oplus B$, $A \otimes B$ by

$$\begin{aligned} (a,b)(R \oplus S)(c,d) \quad & \text{if } (a = c = 0 \text{ and } bRd) \\ & \text{or } (a = 0 \text{ and } c = 1) \\ & \text{or } (a = c = 1 \text{ and } bSd) \\ (a,b)(R \otimes S)(c,d) \quad & \text{if } bSd \\ & \text{and } (\text{if } b = d \text{ then } aRc). \end{aligned}$$

Intuitively, $R \oplus S$ is like a copy of *A* in the *R* order, followed by a copy of *B* in the *S* order, while $R \otimes S$ is like a copy of *B* but with each element replaced by an entire copy of *A*. Then $|R| + |S| = |R \oplus S|$ and $|R| \cdot |S| = |R \otimes S|$.

For ordinals the methods of proof by transfinite induction and definition by transfinite recursion, analogous to the ordinary methods of induction and recursion in higher arithmetic or number theory, are available. To prove by transfinite induction that $\Phi(\rho)$ holds for all ordinals ρ, one must prove, as in finite induction, that $\Phi(0)$ holds and if $\Phi(\rho)$ holds then $\Phi(\rho')$ holds, and additionally that if τ is a limit and $\Phi(\mathbf{\Sigma})$ holds for all $\mathbf{\Sigma} < \tau$, then $\Phi(\tau)$ holds.

Similarly, to define by recursion $\psi(\rho)$ for all ordinals ρ, one must define (1) $\psi(0)$, (2) $\psi(\rho')$ in terms of $\psi(\rho)$, and (3) $\psi(\tau)$ in terms of $\psi(\mathbf{\Sigma})$ for $\mathbf{\Sigma} < \tau$ at limits τ. Equivalent, more convenient, definitions of addition and multiplication, plus a definition of ordinal exponentiation, can be given for ordinals by transfinite recursion:

$$\begin{aligned} \rho + 0 &= \rho & \rho + (\mathbf{\Sigma}^{\#}) &= (\rho + \mathbf{\Sigma})^{\#} \\ \rho \cdot 0 &= 0 & \rho \cdot (\mathbf{\Sigma}^{\#}) &= (\rho \cdot \mathbf{\Sigma}) + \rho \\ \rho^0 &= 1 & \rho^{(\mathbf{\Sigma}^{\#})} &= (\rho^{\mathbf{\Sigma}}) \cdot \rho \end{aligned}$$

and at the limits:

$$\begin{aligned} \rho + \tau &= \sup\{\rho + \mathbf{\Sigma} | \mathbf{\Sigma} < \tau\} \\ \rho \cdot \tau &= \sup\{\rho \cdot \mathbf{\Sigma} | \mathbf{\Sigma} < \tau\} \\ \rho^{\tau} &= \sup\{\rho^{\mathbf{\Sigma}} | \mathbf{\Sigma} < \tau\}. \end{aligned}$$

If $\rho, \mathbf{\Sigma}$ both have cardinality α, then so do $\rho + \mathbf{\Sigma}$, $\rho \cdot \mathbf{\Sigma}$ and even (in contrast to cardinal exponentiation) $\rho^{\mathbf{\Sigma}}$. Note $\rho^{\#} = \rho + 1$. Also $\omega^{\#}$, $\omega^{\#\#}$ and $\omega^{\dagger}$ are $\omega + 1$, $\omega + 2$, $\omega + \omega$.

3 Cardinal numbers and cardinal arithmetic

The cardinal number ('size') of a set is written $||A||$. The order '$\leq$' on the cardinals is defined as follows. $||A|| = ||B||$ if there is a bijection from *A* to *B*, and $||A|| \leq ||B||$ if there is a bijection from *A* to a subset of *B*. This order also has the properties of a well-order, by its connection with ordinal order. Hence there is a least or

zero cardinal. Cantor proved that for any cardinal α there is a greater cardinal and hence a least greater cardinal, its successor, α^+ (an explicit description is given below). For every set *C* of cardinals there is a cardinal greater than or equal to each of its elements, hence a least such cardinal, the supremum of *C*, $\sup C$. If $C = \{\beta | \beta = ||B||$ for some $B \in X\}$, then $\sup C = ||\cup X||$. (Note this implies there can be no set of all cardinals.) A limit (cardinal) is one that is neither zero nor a successor.

As with ordinals, the cardinals 0, $1 = 0^{\#}$, $2 = 1^{\#}, \ldots$ less than the least limit are called finite, and the least limit $\sup\{0, 1, 2, \ldots\}$, the cardinal of the natural numbers, is called $\aleph_0$ ('aleph-nought' or 'aleph-null'). Sets of cardinality $\aleph_0$ are called 'countable'. $\aleph_0^+$ is called $\aleph_1$, and the least ordinal of cardinality $\aleph_1$ is called ω_1 or Ω. $\aleph_1^+$, $\aleph_1^{++}, \ldots$ are called $\aleph_2$, $\aleph_3, \ldots$, and the next limit cardinal $\sup\{\aleph_0, \aleph_1, \aleph_2, \ldots\}$ is called $\aleph_\omega$, while the least ordinals of these cardinals are called ω_2, $\omega_3, \ldots, \omega_\omega$. There is only one ordinal of each finite cardinality (since there is an isomorphism between any two orders on a finite set). Not so for infinite cardinals, since the ordinals $\omega^{\#}$, $\omega^{\#\#}, \ldots, \omega^{\dagger}$ can also be described as the ordinals of certain unnatural well-orders on the natural numbers, namely

$1, 2, 3, \ldots, 0$

$2, 3, 4, \ldots, 0, 1$

$1, 3, 5, \ldots, 2, 4, 6, \ldots, \ldots$

and hence all have cardinality $\aleph_0$. Indeed, Cantor gave an explicit description of α^+ by proving that it is the cardinal of the set of ordinals of cardinality α. It is now customary to identify a cardinal with the least ordinal of that cardinal, so that $\aleph_0 = \omega_0$, and so on.

Cardinal addition, multiplication and exponentiation are defined as follows: $||A|| + ||B|| = ||A \oplus B||$, $||A|| \cdot ||B|| = ||A \otimes B||$ and $||A||$. These agree with the usual arithmetic notions on natural numbers, and some of the usual arithmetic laws generalize from the finite to the infinite (the associative, commutative and distributive laws of addition and multiplication, and the laws of exponents). But there are some differences. Bijections from $\mathbf{N}$ to $\mathbf{N} \oplus \mathbf{N}$ and to $\mathbf{N} \otimes \mathbf{N}$ are suggested by the following.

$(0,0)$	$(0,0)$
$(1,0)$	$(0,1)$
$(0,1)$	$(1,1)$
$(1,1)$	$(1,0)$
$(0,2)$	$(0,2)$
$(1,2)$	$(1,2)$
$(0,3)$	$(2,2)$
$(1,3)$	$(2,1)$
$(0,4)$	$(2,0)$
$(1,4)$	$(0,3)$
$\vdots$	$\vdots$

This shows that $\aleph_0 + \aleph_0 = \aleph_0 \cdot \aleph_0 = \aleph_0$. This result can be generalized in two directions to show (1) that a union of countably many countable sets is countable and (2) that

$$(\aleph_0)^n = \aleph_0 \cdot \ldots \cdot \aleph_0 = ||\mathbf{N} \otimes \ldots \otimes \mathbf{N}|| = \aleph_0$$

for all $n \in \mathbf{N}$, and hence (3) writing $\mathbf{N}^{<\omega}$ for the set of all finite ordered sequences (pairs, triples,…) of natural numbers and $\aleph_0^{<\omega}$ for $\sup\{(\aleph_0)^n | n = 0, 1, 2, \ldots\}$, one has

$$\aleph_0^{<\omega} = ||\mathbf{N}^{<\omega}|| = \aleph_0.$$

These 'abstract' results have 'concrete' counterparts for the sets $\mathbf{Z}$, $\mathbb{Q}$ and $\mathbf{A}$ of integers, rational and algebraic numbers (these last being the real numbers that are roots of polynomial equations with rational coefficients); namely,

$$||\mathbf{Z}|| = ||\mathbb{Q}|| = ||\mathbf{A}|| = \aleph_0.$$

Finally, there is the generalization that $\alpha + \alpha = \alpha \cdot \alpha = \alpha^{<\omega} = \alpha$ for all infinite α, and $\alpha + \beta = \alpha \cdot \beta = \sup\{\alpha, \beta\}$ for all infinite α, β, so cardinal addition and multiplication trivialize.

Exponentiation is not trivial. A bijection between subsets of *A* and functions from *A* to $\{0, 1\}$ is obtainable by relating a subset *B* with its 'characteristic function', χ_B.

$$\chi_B(a) = \begin{cases} 1 & \text{if } a \in B \\ 0 & \text{if } a \notin B \end{cases}$$

Thus $||\wp(A)|| = 2^{||A||}$. Cantor proved that $||A|| < 2^{||A||}$. (Indeed, no function $F : A \rightarrow \wp(A)$ can be a bijection, since $F(a) \neq \{x \in A | x \notin F(x)\}$ for any *a*.)

The cardinal c (for 'continuum') is defined to be $||\mathbb{R}||$, where $\mathbb{R}$ is the set of real numbers (or points in the line). By the general result $||A|| \cdot ||A|| = ||A||$, c is equal to $||\mathbb{R} \otimes \mathbb{R}||$ or $||\mathbb{C}||$, where $\mathbb{C}$ or $\mathbb{R} \otimes \mathbb{R}$ is the set of complex numbers (or points in the plane). It can also be shown to be equal to $||\wp(\mathbb{N})||$ or $2^{\aleph_0}$, and by the general result $||A|| < 2$ one has $\aleph_0 < \mathbf{c}$. A 'concrete' consequence of this 'abstract' result is that there exist transcendental (that is, non-algebraic real) numbers.

The 'generalized continuum hypothesis' is the conjecture that $2^\alpha = \alpha^+$ for all cardinals α. The 'continuum hypothesis' (CH) is the special case for $\alpha = \aleph_0$. Equivalently, CH asserts there is no intermediate cardinal α with $\aleph_0 < \alpha < \mathbf{c}$. The most interesting alternatives to CH include the hypotheses CH': that there is just one such intermediate; and $\mathrm{CH}^{\#}$: that there are c intermediates. Where CH asserts that $\mathbf{c} = \aleph_1$ and CH' asserts that $\mathbf{c} = \aleph_2$, $\mathrm{CH}^{\#}$ implies that $\mathbf{c} > \aleph_1, \aleph_2, \ldots, \aleph_\omega$, and more. Assuming the generalized continuum hypothesis, exponentiation simplifies.

$$\alpha^\beta = \begin{cases} \alpha & \text{if } \beta < \mathrm{cf}\alpha \\ \alpha^+ & \text{if } \mathrm{cf}\alpha \leq \beta < \alpha \\ \beta^+ & \text{if } \mathrm{cf}\alpha < \beta \end{cases}$$

Otherwise, one must distinguish between a cardinal α being a limit, meaning that $\beta^+ < \alpha$ whenever $\beta < \alpha$, and α being a 'strong limit', meaning that $2^\beta < \alpha$ whenever $\beta < \alpha$.

The 'cofinality' $\mathrm{cf}\alpha$ of a cardinal α is the least β such that there is a set *B* of sets with $\beta = ||B||$ and $||b|| < \alpha$ for all sets $b \in B$, but $|| \cup B|| = \alpha$. α is 'regular' or 'singular' according as $\mathrm{cf}\alpha$ is equal to or less than α. $\aleph_0$ is regular (otherwise $\mathrm{cf}\aleph_0$ would be finite, but a union of finitely many finite sets is finite), $\aleph_1$ is regular (otherwise $\mathrm{cf}\aleph_1$ would be $\aleph_0$, but a union of countably many countable sets is countable), and generally α^+ is regular. $\aleph_\omega$ is singular, with $\mathrm{cf}\aleph_\omega = \aleph_0$ (a union of countably many sets with cardinality $\aleph_0$, $\aleph_1$, $\aleph_2$ and so on has cardinality $\aleph_\omega$). It can at least be proved that $\mathbf{c} \neq \aleph_\omega$, and more generally that $\mathrm{cf}2^\alpha > \mathrm{cf}\alpha$.

4 Combinatorial set theory

Analogous to finite combinatorics based on the ordinary arithmetic of the natural numbers there is an extensive 'combinatorial' set theory or infinitary combinatorics based on the transfinite arithmetic of cardinals and ordinals. A typical cardinal result is the 'delta system' theorem: if *A* is an uncountable set of finite sets, then there is a fixed finite set *b* and an uncountable $B \subseteq A$ such that $b' \cap b'' = b$ for all $b', b'' \in B$.

A typical ordinal result is the 'pressing down' theorem. Let *A* be a set of ordinals. *A* is called 'unbounded' in τ if $\sup(A \cap \tau) = \tau$, or for every $\rho < \tau$ there exists $\mathbf{\Sigma} \in A$ with $\rho < \mathbf{\Sigma} < \tau$. Given an uncountable regular cardinal α, *A* is called 'closed' in α if $\tau \in A$ whenever $\tau < \alpha$ and *A* is unbounded in τ. $B \subseteq \alpha$ is called 'stationary' in α if for all sets *A* that are closed and unbounded in α, $B \cap A \neq \emptyset$. The theorem asserts that if *F* is a function from α to α and $\{\rho < \alpha | F(\rho) < \rho\}$ is stationary, then there is a $\mathbf{\Sigma} < \alpha$ such that $\{\rho < \alpha | F(\rho) = \mathbf{\Sigma}\}$ is stationary.

Also included in combinatorial set theory are results about order types other than ordinals, beginning with the theory of the order types η, θ of the usual orders on $\mathbb{Q}$ and $\mathbb{R}$. Given a linear order '$\leq$' on a set *A*, an 'open' interval is a set of the form $]a, b[= \{x | a < x < b\}$ for $a < b$ and a 'closed' interval is a set $[a, b] = \{x | a \leq x \leq b\}$, $a \leq b$. $B \subseteq A$ is 'dense' if it is disjoint from no open interval and 'bounded' if it is a subset of some closed interval. $\leq$ is 'separable' if there exists a countable dense subset *B*, and satisfies the

'countable chain condition' (or 'is CCC') if there exists no uncountable set of disjoint open intervals. (Separability implies CCC since each of a set of disjoint open intervals must contain a distinct element of the countable dense set.) '$\leq$' is 'complete' if every chain of closed intervals has a non-empty intersection. $\mathbb{Q}$, $\mathbb{R}$ are each unbounded and dense in themselves, and $\mathbb{Q}$ is dense in $\mathbb{R}$ (and countable), so $\mathbb{R}$ is separable and CCC. $\mathbb{R}$ is complete, but $\mathbb{Q}$ is not (for example, the intervals

$$\ldots [1.414, 1.415] \subseteq [1.41, 1.42] \subseteq [1.4, 1.5] \subseteq [1, 2]$$

have intersection $\{\sqrt{2}\}$). Cantor proved that any unbounded, dense linear order on a countable set has order type η. Similarly, any unbounded, dense, separable, complete linear order has order type θ. The 'Suslin hypothesis' is that the latter result holds with CCC in place of separability.

5 Point sets

The oldest part of set theory and the part most closely connected with the rest of mathematics (analysis, topology) is the theory of sets of points in the line, plane and so on (identified with $\mathbb{R}, \mathbb{R} \otimes \mathbb{R}, \ldots$). Modern analysis and topology consider more complicated functions and sets than traditional calculus and geometry. A function $F : \mathbb{R} \to \mathbb{R}$ is 'continuous' if $F^{-1}[U]$ is open for every open $U \subseteq \mathbb{R}$, where an 'open' set is a union of open intervals and a 'closed' set is the complement of an open set. The Cantor 'discontinuum', the complement in the unit interval $[0, 1]$ of the union of the open intervals $]\frac{1}{3}, \frac{2}{3}[, \ ]\frac{1}{9}, \frac{2}{9}[, \ ]\frac{7}{9}, \frac{8}{9}[, \ ]\frac{1}{27}, \frac{2}{27}[, \ ]\frac{7}{27}, \frac{8}{27}[, \ ]\frac{19}{27}, \frac{20}{27}[$ and so on, is a famous example of a closed set (see Continuum hypothesis §2) more complicated than any considered in traditional mathematics. Sets obtainable from open sets by iterated application of complementation and countable union are called 'Borel' sets. They occur ubiquitously in modern mathematics (as in the rigorous formulation of probability theory), while sets beyond Borel occur sporadically.

An 'analytic' set is the image of a Borel set under a continuous function, a 'co-analytic' set is the complement of an analytic set, a 'pro-co-analytic' (PCA) set is the image of any set under a continuous function, and a 'co-pro-co-analytic' (CPCA) set is the complement of a pro-co-analytic set. Sets obtainable from Borel sets by iterated application of continuous image and complementation are called 'projective'. Projective sets are rather special compared with arbitrary sets. It can be shown that there are only c projective sets, whereas there are $2^{\mathfrak{c}}$ subsets of $\mathbb{R}$. The study of such special classifications of sets is called 'descriptive' set theory. In one notation, open sets are denoted $\mathbf{\Sigma}^0_1$, closed sets, $\mathbf{\Pi}^0_1$, unions of countably many closed sets, $\mathbf{\Sigma}^0_2$ and their complements, $\mathbf{\Pi}^0_2, \ldots$. Analytic, co-analytic, PCA and CPCA sets are denoted, respectively, $\mathbf{\Sigma}^1_1$, $\mathbf{\Pi}^1_1$, $\mathbf{\Sigma}^1_2$ and $\mathbf{\Pi}^1_2, \ldots$ sets.

Central to attempts to define integration for complicated functions, and length, area and so on for complicated linear, planar,… sets, is the notion of a (complete probability) 'measure' on a set or 'space' *X*. Such a measure is a function μ from the set of '(μ-)measurable' subsets of *X* to the unit interval $\mathrm{J} = [0, 1]$, $\mu(A)$ being called the (μ-)measure of $A \subseteq X$. μ has the following properties: (1) 'normality' - the whole space has measure one; (2) 'non-triviality' - any one-point set has measure zero; (3) 'completeness' - any subset of a set of measure zero has measure zero; (4) 'complementarity' - the complement of a measurable set is measurable; and (5) 'additivity' - the union of a countable set of measurable sets is measurable and, if the sets are disjoint, the measure of their union is the sum of their measures. The analogue of additivity with 'countable set' replaced by 'set of cardinality less than that of the whole space' may be called ($5'$) 'superadditivity'. If we restrict ourselves to the unit interval, the 'translation' of $A \subseteq \mathrm{J}$ by $t \in \mathrm{J}$ is defined to be $\{a \# t | a \in A\}$, where $x \# y$ is defined to be whichever of $x + y$, $x + y - 1$ is an element of J, and one may consider the further property (6) 'invariance' - a translation of a measurable set is measurable, and its measure is the same. The key positive result is the existence of a unique measure on J with properties (1)-(6), called 'Lebesgue measure'. (Analogues can also be defined on $\mathbb{R}, \mathbb{R} \otimes \mathbb{R}$ and so on.) For Lebesgue measure, $\mu(A)$ intuitively represents the probability that a point randomly chosen from J will be an element of *A*. One respect in which the discontinuum is 'pathological' is that it is large in the sense of having cardinality c but small in the sense of having Lebesgue measure 0. (Like some other positive results, the existence and uniqueness of Lebesgue measure require for their proof only DC (see §1 above), not full AC.)

To mention a negative result, the hypothesis that all sets are Lebesgue measurable (AM) fails. Let *S* be a choice set for $\{y \in \mathrm{J} | (y - x) \in \mathbb{Q}\}$. If *S* were measurable, then using invariance it would follow that the disjoint sets of form $\{y \in \mathrm{J} | y \# p \in S\}$ for $p \in \mathbb{Q}$, whose union is all of J, would all have the same measure ε. But then using additivity, μ(J) would have to be $\varepsilon + \varepsilon + \varepsilon + \ldots$, which is 0 or ∞ according as $\varepsilon = 0$ or > 0. The failure of

AM leads to consideration of some alternative hypotheses, notably the hypothesis (known to imply $\sim\mathrm{CH}$ and $\sim\mathrm{CH}'$) of the existence of a measure with properties (1)-(5) for which all sets are measurable, or the hypothesis (known to imply $\mathrm{CH}^{\#}$) of the existence of a measure with properties (1)-(4) and superadditivity for which all sets are measurable. A more positive result using AC may also be mentioned. Given $Q \subseteq \mathbb{R}$ and a continuous *F* from $\mathbb{R}$ to $\mathbb{R}$ a uniformization for *Q*, *F* is a choice set *P* for $\{\{y \in Q|F(y) = F(x)\}|x \in Q\}$. AC immediately implies the existence of a uniformization for any *Q*, *F*.

The failure of AM also leads to consideration of some restricted hypotheses: for Γ one of the special classifications considered above, 'Γ-measurability' is the hypothesis that all sets in Γ are measurable. Similarly, 'Γ-uniformization' is the hypothesis that for any $Q \in \Gamma$ and any continuous *F* there is a uniformization $P \in \Gamma$. It can be shown that while $\mathbf{\Sigma}^1_p$-measurability and $\mathbf{\Pi}^1_p$-measurability imply each other for the same *p*, $\mathbf{\Sigma}^1_p$-uniformization and $\mathbf{\Pi}^1_p$-uniformization cannot both hold for the same *p*. Positive results of descriptive set theory obtained by the end of the 1930s include $\mathbf{\Sigma}^1_1$- and $\mathbf{\Pi}^1_1$-measurability, an example of a 'regularity' theorem or result of the form 'Every set in Γ has some ''nice'' property', and also $\mathbf{\Pi}^1_1$- and $\mathbf{\Sigma}^1_1$-uniformization, an example of a 'structure' theorem or result of the form 'For every set in Γ there is another set in Γ related to it in some ''nice'' way'. All attempts to prove $\mathbf{\Sigma}^1_2$- and $\mathbf{\Pi}^1_2$-measurability, and $\mathbf{\Sigma}^1_3$- or $\mathbf{\Pi}^1_3$-uniformization have failed.

6 New axioms for set theory: large cardinals and determinacy

Beginning in about 1940, many conjectures Δ (including those mentioned at the end of §5) have been proved by mathematical logicians to be 'undecidable' relative to ZFC, meaning that it has been shown that if ZFC is consistent, then so are both $\mathrm{ZFC} + \Delta$ (relative consistency of Δ) and $\mathrm{ZFC}+\sim\Delta$ (relative independence of Δ). Note that the consistency of ZFC, let alone of $\mathrm{ZFC} + \Delta$ (or $\mathrm{ZFC}+\sim\Delta$), cannot be proved within ZFC itself, by celebrated results of mathematical logic (see Gödel's theorems), and hence cannot be proved by ordinary mathematical methods, since these can be developed within ZFC. The most one can hope to prove is the *relative* result that if a contradiction could be deduced from $\mathrm{ZFC} + \Delta$ (or $\mathrm{ZFC}+\sim\Delta$), then a contradiction could be deduced from ZFC. There are two basic methods for proving relative consistency. A first method was used by Kurt Gödel to prove the consistency of CH relative to ZFC (and of AC relative to ZF) (see Constructible universe). A second method was used by Paul Cohen to prove the independence of CH relative to ZFC (and of AC relative to ZF) (see Forcing). Both methods have been widely applied since.

For some hypotheses, however, there can be no hope of a proof of relative consistency, namely for any hypothesis that itself implies the consistency of ZFC. An example is the hypothesis of the existence of an 'inaccessible' or regular strong limit cardinal α (IC). (How IC implies the existence of a model of ZFC, and hence the consistency of ZFC, will be indicated in §7.) Even in such cases there may be heuristic or inductive evidence of consistency (failure to deduce a consequence in years of work with the hypothesis). In order to decide questions undecidable in ZFC, new axioms have from time to time been advocated. The two kinds most often advocated (which unfortunately still leave CH undecided) have been 'large cardinal' and 'determinacy' axioms. The former, which pertain to sets larger than any encountered in ordinary mathematical practice, are often advocated on the intrinsic ground that they are further expressions of intuitions only partly expressed by the ZFC axioms (to the effect that the hierarchy of sets is 'tall'). The latter, which pertain to special classifications of sets of linear, plane,… points, and are connected with problems in analysis and topology, are often advocated on the extrinsic ground that their consequences are 'nice'.

Large cardinal axioms include IC and also MC, the hypothesis that there exists a measurable cardinal β. Here β is measurable if there is a superadditive measure (as defined in §5), taking only the two values 0 and 1, for which all subsets of β are measurable. It follows from non-triviality and superadditivity that any subset of cardinality $< \beta$ will have measure 0, and by superadditivity again that any union of a set of cardinality $< \beta$ of such subsets will still have measure 0, whence β is regular. It also follows that if $\alpha < \beta$ and *F* is a function from β to $\wp(\alpha)$, then for any $\rho < \alpha$ one of the sets

$$D^+(\rho) = \{\mathbf{\Sigma} < \beta|\rho \in F(\mathbf{\Sigma})\}$$
$$D^-(\rho) = \{\mathbf{\Sigma} < \beta|\rho \notin F(\mathbf{\Sigma})\}$$

will have measure 0, the other, measure 1, and by superadditivity the union *D* of the ones with measure 0 will have

measure 0. But for $\mathbf{\Sigma}, \tau \notin D$ one has

$F(\mathbf{\Sigma}) = F(\tau) = \{\rho < \alpha | \mu(D^+(\rho)) = 1\}$

so *F* is not a bijection, $2^\alpha = ||\wp(\alpha)|| < \beta$, and β is a strong limit. So a measurable cardinal β is inaccessible, and indeed it can even be shown that $\{\alpha < \beta | \alpha$ is an inaccessible $\mathrm{cardinal}\}$ has cardinal β, so MC is a much stronger hypothesis than IC. Still stronger is the hypothesis (SC) that there exists a 'supercompact' cardinal γ. For such a γ there is for any $\delta > \gamma$ an analogue of a measure as above for the subsets of δ of cardinality γ.

Determinacy axioms pertain to certain infinite games considered in mathematical game theory. Given $A \subseteq$ J there is a game for two players I, II: they alternately pick the terms in the decimal expansion of a real *x*, and I or II wins according as *x* is or is not an element of *A*. A 'strategy' for a player is, intuitively, a rule telling the player how to play as a function of the opponent's previous moves, and is winning if by so playing the player will win the game, no matter what the opponent's moves. *A* is 'determinate' if one or other player has a winning strategy. $\mathbf{\Pi}^1_1$-AD, PD and AD (to add to the notation set up in §5) are, respectively, the hypotheses that all $\mathbf{\Pi}^1_1$, projective or arbitrary sets are determinate. AD is refutable using AC, among other reasons because AD implies AM, while, by essentially the same proof, PD implies projective measurability, and various other regularity theorems. Similarly, PD implies projective uniformization and various other structural theorems. $\mathbf{\Pi}^1_1$-AD yields, correspondingly, $\mathbf{\Sigma}^1_2$- and $\mathbf{\Pi}^1_2$-measurability and $\mathbf{\Pi}^1_3$-uniformization.

Despite superficial differences, there are deep connections between large cardinals and determinacy. By the 1970s it was established that a large cardinal axiom somewhat weaker than MC implies a conclusion somewhat stronger than $\mathbf{\Pi}^1_1$-AD, with the partial converse that such a determinacy hypothesis implies the consistency of such a large cardinal hypothesis. In the 1980s an analogous relation between SC and PD was established. So the cases for large cardinal and for determinacy axioms reinforce each other. The search for further axioms to decide CH continues.

7 Models of set theory

In Gödel's method for proving relative consistency of a conjecture Δ, one seeks a formula $\Xi(x)$ and proves that for any axiom of $\mathrm{ZFC} + \Delta$ and hence for any finite conjunction Ψ of such axioms, Ψ^Ξ is provable in ZFC, where Ψ^Ξ is the result of replacing each quantifier 'for all *x*' or 'for some *x*' in Ψ by the 'restricted' quantifier 'for all *x* such that $\Xi(x)$' or 'for some *x* such that $\Xi(x)$'.

Supposing this had been done, if a contradiction could be deduced from $\mathrm{ZFC} + \Delta$, the deduction would use only finitely many of the axioms of $\mathrm{ZFC} + \Delta$, and so a contradiction $\Theta \text{ and } {\sim}\Theta$ could be deduced from some finite conjunction Ψ of axioms of $\mathrm{ZFC} + \Delta$ and, restricting quantifiers, a contradiction $\Theta^\Xi \text{ and } {\sim}\Theta^\Xi$ could be deduced from Ψ^Ξ. By exhibiting the deduction of a contradiction from Ψ^Ξ, ${\sim}\Psi^\Xi$ would be provable in ZFC, and hence a contradiction (both Ψ^Ξ and ${\sim}\Psi^\Xi$) would be deducible in ZFC. Such a Ξ (and derivatively, the 'universe' of all *x* such that $\Xi(x)$ holds) is said to constitute an 'inner model'.

In Cohen's method for proving relative consistency, one assumes the existence of a set *X* that is a model of ZFC in the sense that for any axiom of ZFC, and hence for any finite conjunction Φ of such axioms, Φ^X holds, where Φ^X is the result of replacing each quantifier in Φ by the restricted quantifier (as above). One then proves the existence of a set *Y* that is a model of $\mathrm{ZFC} + \Delta$, but in such a way that for any finite conjunction Ψ of axioms of $\mathrm{ZFC} + \Delta$, the proof that Ψ^Y holds depends only on the assumption that Φ^X holds for some finite conjunction $\Phi = \Phi_\Psi$ of axioms of ZFC. Supposing this done, one uses the fact that while the existence of a model *X* of all of ZFC cannot be proved in ZFC (since this would imply the consistency of ZFC), for any finite conjunction Φ of axioms of ZFC the existence of a model of Φ can be proved in ZFC (as will be indicated below). It follows that the existence of a model for any finite subset Ψ of $\mathrm{ZFC} + \Delta$ is provable in ZFC. Then if a contradiction could be deduced from $\mathrm{ZFC} + \Delta$, a contradiction could be deduced from some finite conjunction Ψ of axioms of $\mathrm{ZFC} + \Delta$, and by exhibiting this deduction the non-existence of any model of Ψ could be proved in ZFC, and hence a contradiction (existence and non-existence of a model of Ψ) could be proved in ZFC.

The general theories of set models *X* (as in the second method) and formula models Ξ (as in the first method) are closely parallel, and only the theory of set models will be sketched here. For applications it suffices to consider only sets *X* that are 'transitive' in the sense that whenever $u \in v \in X$, then $u \in X$. Informally, if Φ^X holds, it will be said that it 'appears' to *X* that Φ holds, or that Φ holds 'inside' *X*. Central to the theory of models is the

determination of sufficient conditions for various axioms of ZFC to hold inside *X*. Central to this determination are considerations of absoluteness, where a formula Φ is called 'absolute' for *X* if for any $u, v, \ldots \in X$, $\Phi(u, v, \ldots)$ appears to *X* to hold if and only if it really holds. This will always be so if Φ is a 'limited' formula, mentioning only $u, v,$ and their elements, elements of elements and so on, since by transitivity these will all be elements of *X*.

For instance, the condition 'u, v have different elements' or 'For some *w*, either $w \in u$ and $w \notin v$ or $w \in v$ and $w \notin u$' is limited, and so $u, v \in X$ appear to *X* to have different elements if and only if they really do have different elements, and so the axiom of extensionality, 'For every u, v, if $u \neq v$ then u, v have different elements', holds inside *X* for any transitive *X*. Similarly, it can be shown that the axiom of foundation holds inside *X* for any transitive *X*. As for pairing, the condition '$w = \{u, v\}$' or '$u \in w$ and $v \in w$ and for all $z \in w$, $z = u$ or $z = v$' is limited, and so *w* appears to *X* to be the pair $\{u, v\}$ of u, v if and only if it really is that pair, and so the axiom of *pairs*, 'For every u, v there exists a *w* such that $w = \{u, v\}$', holds inside *X* if and only if $\{u, v\} \in X$ whenever $u, v \in X$, or, as is said, if and only if *X* is closed under the pairing operation $\{\ ,\ \}$. Similarly it can be shown that the axiom of *union* holds in *X* if and only if *X* is closed under the union operation '$\cup$'; that the axiom of infinity holds in *X* if and only if $\omega \in X$; and that the axiom of choice holds in *X* if and only if every partition in *X* has a choice set in *X*.

As for power, *u* appears to *X* to be a subset of *v* if and only if it really is, but *w* appears to *X* to be the set $\wp(v)$ of all subsets *u* of *v* if and only if *w* really is the set $\wp(v) \cap X$ of all subsets *u* of *v* with $u \in X$. Thus the axiom of *power* appears to *X* to hold if and only if *X* is closed under the operation of forming $\wp(v) \cap X$ from *v*, which may be the case even if *X* does not contain all subsets of *v* and therefore is not closed under the operation of forming $\wp(v)$ from *v*. Similarly, a necessary and sufficient condition for separation to hold inside *X* is that for each condition Φ, *X* is closed under the operation that applies to any *v* forms $\{u \in v | \Phi^X(u)\}$. Similarly, a necessary and sufficient condition for replacement to hold inside *X* is that for each condition Φ such that for every $x \in X$ there is a unique $y = \psi^X(x) \in X$ such that $\Phi^X(x, y)$ holds, *X* is closed under the operation that applied to *v* forms $\{\psi^X(u) | u \in v\}$. *X* is 'supertransitive' if whenever $u \subseteq v \in X$, then $u \in X$. For supertransitive *X*, $\wp(v) \cap X = \wp(v)$ for any $v \in X$, so the necessary and sufficient condition for power to hold is just that *X* is closed under the power operation $\wp$. Supertransitivity is a more than sufficient condition for separation to hold. Similarly, a more than sufficient condition for replacement to hold is that whenever $u \subseteq X$, $||u|| = ||v||$ and $v \in X$, then $u \in X$.

One kind of model of a large part of ZFC is obtained as follows. For any *x* let the 'transitivization' $t(x)$ of *x* be $\cup\{x, \cup x, \cup\cup x, \ldots\}$, the set of all elements, elements of elements and so on of *x*. For any uncountable cardinal α, let $H(\alpha)$ be $\{x | \alpha > ||t(x)||\}$. It follows from the definition that $H(\alpha)$ is supertransitive, and it can be checked, using the necessary and sufficient conditions indicated above, that $H(\alpha)$ is a model of all axioms of ZFC except perhaps power and replacement. Moreover, if α is a strong limit, then $H(\alpha)$ will be closed under $\wp$ and hence a model of power; while if α is regular, then one will have $u \in H(\alpha)$ whenever $u \subseteq H(\alpha)$, $||u|| = ||v||$, $v \in H(\alpha)$ and $H(\alpha)$ will be a model of replacement. (Thus if α is inaccessible, $H(\alpha)$ is a model of the whole of ZFC.)

Another kind of model of a large part of ZFC is obtained as follows. The hierarchy of levels of sets, intuitions about which underlie the axioms (as in §1), can be defined by transfinite recursion.

$$
\begin{aligned}
V(0) &= \emptyset \\
V(\rho+1) &= \wp(V(\rho)) \\
\text{at limits } V(\tau) &= \cup\{V(\boldsymbol{\Sigma}) | \boldsymbol{\Sigma} < \tau\}
\end{aligned}
$$

That $V(\rho)$ is supertransitive can be proved by transfinite induction. Given the other axioms of ZFC, the principle of replacement can be proved equivalent to the following principle of 'reflection': for any formula Φ there are arbitrarily large ordinals ρ such that Φ is absolute for $V(\rho)$. In particular, for any finite conjunction Φ of axioms of ZFC there are arbitrarily large ordinals ρ such that Φ holds in $V(\rho)$.

While both the $V(\rho)$ (for $\rho > \omega$) and the $H(\alpha)$ (for $\alpha > \aleph_0$) are uncountable, it can be shown that if a ZFC or some variant set theory has a transitive model, then it has a countable transitive model, using a celebrated result of mathematical logic (see Löwenheim-Skolem theorems and nonstandard models). Since the uncountability of the

power set of the set of natural numbers is a theorem of set theory, the existence of a countable model for set theory is sometimes considered paradoxical, and called the ‘Skolem paradox’. There is, however, no genuine contradiction. (For the conditions ‘ $x = \wp(\omega)$’ and ‘ $||x|| > \aleph_0$’ are not absolute: the former holds inside a model *X* if $x = \wp(\omega) \cap X$, which may well be countable even though $\wp(\omega)$ is uncountable; the latter holds inside the model *X* if there is no surjection $F \in X$ from ω to *x*, which there may well not be even if there is such an $F \notin X$.)

Set theory, different systems of

To begin with we shall use the word 'collection' quite broadly to mean anything the identity of which is solely a matter of what its members are (including 'sets' and 'classes'). Which collections exist? Two extreme positions are initially appealing. The first is to say that all do. Unfortunately this is inconsistent because of Russell's paradox: the collection of all collections which are not members of themselves does not exist. The second is to say that none do, but to talk as if they did whenever such talk can be shown to be eliminable and therefore harmless. This is consistent but far too weak to be of much use. We need an intermediate theory.

Various theories of collections have been proposed since the start of the twentieth century. What they share is the axiom of 'extensionality', which asserts that any two sets which have exactly the same elements must be identical. This is just a matter of definition: objects which do not satisfy extensionality are not collections. Beyond extensionality, theories differ. The most popular among mathematicians is Zermelo-Fraenkel set theory (ZF). A common alternative is von Neumann-Bernays-Gödel class theory (NBG), which allows for the same sets but also has proper classes, that is, collections whose members are sets but which are not themselves sets (such as the class of all sets or the class of all ordinals).

Two general principles have been used to motivate the axioms of ZF and its relatives. The first is the iterative conception, according to which sets occur cumulatively in layers, each containing all the members and subsets of all previous layers. The second is the doctrine of limitation of size, according to which the 'paradoxical sets' (that is, the proper classes of NBG) fail to be sets because they are in some sense too big. Neither principle is altogether satisfactory as a justification for the whole of ZF: for example, the replacement schema is motivated only by limitation of size; and 'foundation' is motivated only by the iterative conception.

Among the other systems of set theory to have been proposed, the one that has received widespread attention is Quine's NF (from the title of an article, 'New Foundations for Mathematical Logic'*), which seeks to avoid paradox by means of a syntactic restriction but which has not been provided with an intuitive justification on the basis of any conception of set. It is known that if NF is consistent then ZF is consistent, but the converse result has still not been proved.*

1 Virtual collections

Sometimes when we speak of collections it is just a manner of speaking and no more: if we say that Sarah belongs to the collection of all linguists, we might just as well say straight away that she is a linguist; nothing seems to be lost in the translation. This way of regarding collections is quite old: it is how Peano conceived of them in the 1880s. If we already have before us some formal theory which does not have collection-talk in it, then we can add it straightforwardly. If $\Phi(x)$ is a formula of the theory in question, we introduce a new term $\{x\colon \Phi(x)\}$ (called a 'collection term') into the language. Collection terms are subject to the following two rules:

(1) If $\Phi(x)$ is a formula then $x \in \{y\colon \Phi(y)\}$ is an abbreviation for $\Phi(x)$.
(2) If $\Phi(x)$ and $\Psi(x)$ are both formulas of the theory then $\{x\colon \Phi(x)\} = \{x\colon \Psi(x)\}$ is an abbreviation for $\forall x(\Phi(x) \leftrightarrow \Psi(x))$.

We permit the use of collection terms only in contexts from which these two rules allow them to be eliminated. Collections used harmlessly in this way have been called 'virtual' by Quine and we shall follow this terminology here. Let us introduce the convention that lower-case Greek letters stand schematically for collection terms. So the second re-writing rule allows us to assert, for instance, the following *extensionality schema*:

$\forall z(z \in \alpha \leftrightarrow z \in \beta) \rightarrow \alpha = \beta.$

By this schematic device we generate a considerable amount of the naïve theory of collections. We can, for instance, introduce the usual Boolean operations as follows:

$$\alpha \cap \beta = \{x\colon\ x \in \alpha \wedge x \in \beta\}$$
$$\alpha \cup \beta = \{x\colon\ x \in \alpha \vee x \in \beta\}$$
$$\emptyset = \{x\colon\ x \neq x\}$$
$$\mathbf{V} = \{x\colon\ x = x\}$$
$$\{x\} = \{y\colon\ y = x\}$$
$$\{x, y\} = \{x\} \cup \{y\}$$

and so on. The theory thus generated is elegant enough in itself, but it is difficult to be satisfied with it for long. (We have to remember, for instance, that in this theory expressions such as $\{x, y\}$ are merely notational devices and do not, despite the appearance to the contrary that their 'explicit' definitions might suggest, have any meaning on their own.) Collection terms stand in sentences in some of the places where the grammar leads us to expect proper names; schematic letters stand where we might expect variables. There is a drive to objectify at work here; to suppose that collection terms can stand in *all* the places where names can occur. It is of course this step which, if carelessly done, leads straight to contradiction. How to do it without contradiction will be the subject of the rest of this entry.

2 Real collections

In the virtual theory just discussed the relation of membership is defined contextually. In the real theory with collections regarded as objects in their own right membership is taken by almost all authors as primitive. (Lewis (1991) is a rare exception.) Formally, this means that the language in which the theory is couched contains, in addition to the usual logical constants, a binary predicate symbol '$\in$'. It will be convenient to introduce a few notational conventions straight away. Upper-case Greek letters such as Φ and Ψ will stand for formulas. The notation $\Phi(x)$ stands for a formula in which the variable x occurs free: it does not indicate that no other variable occurs free in the formula. If Φ is a formula, we write $\Phi^{(a)}$ for the 'relativization' of Φ to a, that is, the formula obtained from Φ by replacing each quantifier $\forall x$ or $\exists x$ by $(\forall x \in a)$ or $(\exists x \in a)$, as the case may be. We write $x \subseteq y$ as an abbreviation for $\forall z(z \in x \rightarrow z \in y)$. We introduce ordered pairs by means of the device

$$(x, y) = \{\{x\}, \{x, y\}\}.$$

In the virtual theory, the question of whether there are any objects which are not collections is scarcely an issue: since there are not really any collections, if there is nothing else then there is nothing at all; the theory therefore collapses into vacuity. In any non-trivial real theory things are different: there are plenty of collections to talk about, whether or not there are any non-collections. Since this issue arises uniformly for all the real theories we shall be discussing, it is best to address it now. The objects of a theory which are not collections are called 'atoms', 'individuals' or (even in some non-German texts) '*Urelemente*'. If we are to allow for their presence, we need a primitive unary predicate $\mathrm{atom}(x)$ to represent that x is an atom. We then introduce as an axiom the *axiom of extensionality* (*applied form*):

$$\forall x \forall y(\mathrm{atom}(x) \vee \mathrm{atom}(y) \vee \forall z(z \in x \leftrightarrow z \in y) \rightarrow x = y).$$

This asserts no more than that objects which are not atoms are collections, since (as we have already observed) it is part of what we mean by a collection that it is completely determined by its members. If the atoms are to play any role in the theory at all, we shall also need the *collection axiom*, which states that the atoms form a collection:

$$\exists y \forall x(x \in y \leftrightarrow \mathrm{atom}(x)).$$

If, on the other hand, it is pure collections that interest us, then the beginnings of the theory are a little more concise. We do not need the predicate 'atom(x)' nor the collection axiom, and we can use the simpler *axiom of extensionality* (*pure form*):

$$\forall x \forall y(\forall z(z \in x \leftrightarrow z \in y) \rightarrow x = y).$$

Throughout what follows we shall state theories in their pure form and adopt the convention that if *T* is a pure theory (that is, one which includes the pure form of the axiom of extensionality) then *TU* is the corresponding applied theory (that is, the one obtained from *T* by deleting the pure form of extensionality and substituting the

applied form together with the collection axiom). In the virtual theory we had collection terms defined contextually, provided that they occurred in certain positions (on the right of the '$\in$' symbol or on either side of the '$=$' symbol). Now that we are regarding collections as real we cannot be so indiscriminate. Let us say that a formula $\Phi(x)$ is 'collectivizing' in x for a theory *T* if

$$T \vdash \exists y \forall x (x \in y \leftrightarrow \Phi(x)).$$

Suppose now that *T* includes extensionality among its axioms. If $\Phi(x)$ is collectivizing in x for *T* then, by extensionality, we have uniqueness:

$$T \vdash \exists ! y \forall x (x \in y \leftrightarrow \Phi(x)).$$

It is therefore legitimate to introduce a term $\{y\colon \Phi(y)\}$ with the property that

$$\forall x (x \in \{y\colon \Phi(y)\} \leftrightarrow \Phi(x)).$$

We thereby retrieve the virtual theory of §1 but limited to collectivizing formulas. What remains is to specify which formulas are collectivizing; it is this that is dealt with differently in the various competing theories.

3 Zermelo-Fraenkel set theory

In 1908 Ernst Zermelo published the first axiomatization of set theory. His choice of axioms seems to have been driven largely by his desire to ground a proof of the well-ordering theorem (see Axiom of choice §2; Set theory §2), which he published in the same year. Zermelo's axioms were those of ZCU^- (that is, the applied form of Z^- plus the axiom of choice) except that the axiom of infinity was replaced by Zermelo's own form (see below).

Although Zermelo's system is strong enough for many mathematical purposes, it is weaker than ZCU^- in one important respect: in it, it is impossible to develop a satisfactory theory of ordinal numbers (see Set theory §2). During the 1920s this problem was solved in two ways: ingenious methods were found, principally by Kuratowski (1921), of achieving without ordinals what is most naturally done with them; and Zermelo's system was strengthened, principally by Fraenkel and Skolem, so as to permit the theory of ordinals to be embedded in it. Zermelo-Fraenkel set theory (ZF) was the result.

We start by listing the axioms of a fragment of Zermelo-Fraenkel set theory called Z^-.

Axiom of extensionality. As before.
Axiom schema of separation. If $\Phi(x)$ is a formula in which y does not occur free, then this is an axiom:

$$\forall z \exists y \forall x (x \in y \leftrightarrow x \in z \wedge \Phi(x)).$$

$$Empty\ set\ axiom\colon \exists x \forall y\ y \notin x.$$

$$Pairing\ axiom\colon \forall x \forall y \exists z (x \in z \wedge y \in z).$$

$$Union\ set\ axiom\colon \forall a \exists x \forall y \forall z ((z \in y \wedge y \in a) \rightarrow z \in x).$$

$$Power\ set\ axiom\colon \forall x \exists y \forall z (z \subseteq x \rightarrow z \in y).$$

$$Axiom\ of\ infinity\colon \exists x (\emptyset \in x \wedge \forall y \forall z ((y \in x \wedge z \in x) \rightarrow y \cup \{z\} \in x).$$

To get Z we add:

$$Axiom\ of\ foundation\colon \forall x (x \neq \emptyset \rightarrow (\exists y \in x) x \cap y = \emptyset).$$

(See Set theory §1 for an alternative formulation.) To get ZF we add:

Axiom schema of replacement. If $\Phi(x, y)$ is a formula in which z does not occur free then this is an axiom:

$$\forall a ((\forall x \in a) \exists ! y \Phi(x, y) \rightarrow \\ \exists z (\forall x \in a)(\forall y \in z) \Phi(x, y)).$$

To get ZFC we add:

$$Axiom\ of\ choice\colon \forall a \exists b (\forall x \in a)(x \neq \emptyset \rightarrow \exists ! y (y \in x \cap b)).$$

Many other variants are possible. Below are some examples.

(1) In the presence of the replacement schema the exact form of the axiom of infinity is not critical: any axiom asserting the existence of a set which can be proved to be infinite will do. Two popular choices are the following. *Axiom of infinity (weak form)*:

$$\exists x(\emptyset \in x \wedge \forall y(y \in x \rightarrow y \cup \{y\} \in x).$$

Axiom of infinity (Zermelo's form):

$$\exists x(\emptyset \in x \wedge \forall y(y \in x \rightarrow \{y\} \in x).$$

(2) In ZF^{-} (that is, ZF without foundation) and stronger theories the pairing axiom is redundant.
(3) The separation and replacement schemata and the union set axiom can be amalgamated into the following single schema.
Axiom schema of selection and union. If $\Phi(x, y)$ is a formula in which a and b do not occur free, then this is an axiom:

$$\forall y \exists a \forall x(\Phi(x, y) \rightarrow x \in a) \rightarrow$$
$$\forall b \exists z \forall x(x \in z \leftrightarrow (\exists y \in b)\Phi(x, y)).$$

4 Von Neumann-Bernays-Gödel class theory

Zermelo-Fraenkel set theory is adequate for almost all mathematical purposes. However, its restrictions can sometimes be inconvenient. Mathematicians who use ZF and its variants are therefore accustomed to using the device of virtual sets (see §1 above), except that in order to distinguish virtual sets from the real thing they are called virtual *classes*. If we stop there, we have a good compromise: the technical simplicity of ZF plus the convenience of virtual classes when we need them. However, the urge to treat virtual objects as real is strong, and there is a popular alternative, von Neumann-Bernays-Gödel class theory (NBG), which allows us to say the same things but with classes treated as real.

Before we state the axioms of NBG we need to express what it is for a relation to be 'functional': we do this by writing $\mathrm{func}(r)$ as an abbreviation for the formula $\forall x \forall y \forall z(((x, y) \in r \wedge (x, z) \in r) \rightarrow y = z)$.

$Axiom\ of\ extensionality$: As before.

$Axiom\ of\ classes$: $\exists x \forall y((\exists z\ y \in z) \rightarrow y \in x)$.

$Empty\ set\ axiom$: $\exists x(\forall y\ y \notin x \wedge \exists z\ x \in z)$.

$Pairing\ axiom$: $(\forall x \in \mathbf{V})(\forall y \in \mathbf{V})(\exists z \in \mathbf{V})\forall u(u \in z \leftrightarrow u = x \vee u = y)$.

Axiom schema of class existence. If Φ is any formula with free variables $v_1, v_2, \ldots, v_n$ then this is an axiom:

$$(\forall v_1, v_2, \ldots, v_n \in \mathbf{V})$$
$$\exists z \forall x(x \in z \leftrightarrow (x \in \mathbf{V} \wedge \Phi^{(\mathbf{V})}).$$

$Union\ set\ axiom$: $(\forall x \in \mathbf{V})(\exists y \in \mathbf{V})\forall u(u \in y \leftrightarrow \exists v(u \in v \wedge v \in x))$.

$Power\ set\ axiom$: $(\forall x \in \mathbf{V})(\exists y \in \mathbf{V})\forall u(u \in y \leftrightarrow u \subseteq x)$.

$Axiom\ of\ infinity$: $(\exists x \in \mathbf{V})(\emptyset \in x \wedge (\forall u \in x)(\forall v \in x)(u \cup \{v\} \in x))$.

$Axiom\ of\ replacement$: $(\forall x \in \mathbf{V})\forall r(\mathrm{func}(r) \rightarrow (\exists y \in \mathbf{V})\forall u(u \in y \leftrightarrow (\exists v \in x)(v, u) \in r))$.

$Axiom\ of\ foundation$: As before.

Most of these axioms are unexciting transcriptions of the axioms of ZF. However, there is one striking difference: the axiom schema of replacement has turned into a single axiom. Even more surprisingly, the axiom schema of class existence can also be replaced by a finite list of axioms, such as the following.

$\exists a(\forall x, y \in \mathbf{V})((x, y) \in a \leftrightarrow x \in y)$
$\forall a \forall b \exists c \forall x(x \in c \leftrightarrow (x \in a \wedge x \in b))$
$\forall a \exists b(\forall x \in \mathbf{V})(x \in b \leftrightarrow x \notin a)$
$\forall a \exists b(\forall x \in \mathbf{V})(x \in b \leftrightarrow (\exists y \in \mathbf{V})((x, y) \in a))$
$\forall a \exists b(\forall x, y \in \mathbf{V})((x, y) \in b \leftrightarrow x \in a)$
$\forall a \exists b(\forall x, y, z \in \mathbf{V})((x, y, z) \in b \leftrightarrow (y, z, x) \in a)$
$\forall a \exists b(\forall x, y, z \in \mathbf{V})((x, y, z) \in b \leftrightarrow (x, z, y) \in a)$

So NBG is finitely axiomatizable. This is quite striking since, by contrast, ZF cannot be finitely axiomatized (if it is consistent). And yet NBG and ZF are of equal strength, in the sense that if Φ is any formula in the language of set theory then

$\mathrm{ZF} \vdash \Phi$ if and only if $\mathrm{NBG} \vdash \Phi^{(\mathbf{V})}$.

And moreover, NBG is consistent if and only if ZF is consistent.

Once we have taken the step of regarding classes as objects, it is puzzling why we should constrain the class existence schema by insisting that the formula defining a class can mention only sets, not proper classes. So if we are serious about the reification of proper classes, we should replace the class existence schema with the following.

Morse-Kelley schema. If $\Phi(x)$ is any formula in which y does not occur free then this is an axiom:

$\exists y \forall x(x \in y \leftrightarrow (x \in \mathbf{V} \wedge \Phi(x)))$.

The system thus obtained is known as Morse-Kelley class theory (MK; see Kelley 1955). It is (if consistent) a genuine extension of NBG, even with respect to sets. In other words, there are formulas Φ such that $\mathrm{MK} \vdash \Phi^{(\mathbf{V})}$ but $\mathrm{NBG} \nvdash \Phi^{(\mathbf{V})}$. However, the difficulty now is to know why we should stop: if classes are sufficiently real to occur legitimately in the definitions of sets, there seems no good reason why they should not be members of still more collections. As long as we refrain from calling the new collections thus countenanced ‘sets’ or ‘classes’, there is no fresh danger of inconsistency. Theories arranged in this way are not popular, though, despite their practical convenience.

5 Other axiomatizations

So far we have said little about the motivation for the axioms. Two principles have guided traditional accounts of this question: the iterative conception; and the doctrine of limitation of size. However, it is not easy to justify all the axioms of ZF on the basis of either principle on its own: for example, the replacement schema is motivated only by limitation of size; and foundation is motivated only by the iterative conception.

Other axiomatizations have been given which are closer in spirit to these principles. Here we shall describe two. The first is Scott’s way of axiomatizing the iterative conception of set, according to which sets are divided up into ‘levels’ (see Scott 1974). The set of all levels belonging to a given level is called its ‘history’. The formal details are as follows. First define the ‘accumulation’ of a set to be the set of all the elements and subsets of its members (if this set exists):

$\mathrm{acc}(a) = \{x\colon (\exists b \in a)(x \in b \vee x \subseteq b)\}$.

Next define the predicate ‘history(*a*)’ to be an abbreviation for

$(\forall b \in a) b = \mathrm{acc}(b \cap a)$.

Then define ‘level(*b*)’ to be an abbreviation for

$\exists a(\mathrm{history}(a) \wedge b = \mathrm{acc}(a))$.

Now adopt the convention that the variables V, V', V'' are restricted to range over levels, so that, for instance, $\forall V \ldots$ is an abbreviation for $\forall V(\mathrm{level}(V) \rightarrow \ldots)$. Then the axioms of Z' are as follows:

Axiom of extensionality: As before.

$Axiom\ schema\ of\ separation$: As before.

$Axiom\ of\ creation$: $\forall x \exists V\ x \in V$.

$Axiom\ of\ infinity$: $\exists V (\forall V' \in V)(\exists V'' \in V)(V' \in V'')$.

The axioms of ZF' are as follows:

$Axiom\ of\ extensionality$: As before.

$Axiom\ schema\ of\ separation$: As before.

Axiom schema of reflection. If $\Phi(x)$ is any formula then this is an axiom:

$$\exists V (\forall x \in V)(\Phi(x) \to \Phi^{(V)}(x)).$$

Then Z' is equivalent to Z and ZF' is equivalent to ZF.

The second theory we shall describe is due to Ackermann (1956). It takes $\mathbf{V}$ as a primitive constant. The axioms of the system A are as follows.

$Axiom\ of\ extensionality$: As before.

$Axiom\ schema\ of\ separation$: As before.

$Axiom\ of\ transitivity$: $\forall x \forall y (x \in y \wedge y \in \mathbf{V} \to x \in \mathbf{V})$.

$Axiom\ of\ subsets$: $\forall x \forall y (x \subseteq y \wedge y \in \mathbf{V} \to x \in \mathbf{V})$.

Ackermann's schema. If Φ is a formula in which the free variables are $v_1, v_2, \ldots, v_n$ and in which $\mathbf{V}$ does not occur, then this is an axiom:

$$(\forall v_1, v_2, \ldots, v_n \in \mathbf{V})(\forall x(\Phi(x) \to x \in \mathbf{V}) \\ \to (\exists y \in \mathbf{V})\forall x(x \in y \leftrightarrow \Phi(x))).$$

The motivation for A is not that of the iterative conception; rather, it is based on the idea that anything formed solely from sets is itself a set. The modified system A^* is something of a hybrid: it grafts onto A the following axiom, which is derived from the iterative conception and cannot be justified by the motivating idea of A:

$Axiom\ of\ foundation$: $(\forall x \in \mathbf{V})(x \neq \emptyset \to (\exists y \in x)(y \cap x = \emptyset))$.

If Φ is a formula in which the constant $\mathbf{V}$ does not occur, then

(1) if $\mathrm{Z}^- \vdash \Phi$ then $\mathrm{A} \vdash \Phi^{(\mathbf{V})}$;
(2) $\mathrm{A}^* \vdash \Phi^{(\mathbf{V})}$ if and only if $\mathrm{ZF} \vdash \Phi$.

6 Anti-foundation axioms

We have already mentioned that not all the axioms of ZF can be motivated by any one account of the notion of sethood. In particular, the axiom of foundation cannot be sustained solely on the basis of the doctrine of limitation of size. But without it where do sets get their individuation? To tell whether two sets are equal we compare their members; if necessary, we compare *their* members, and so on. In the presence of the axiom of foundation, this process cannot go on indefinitely; in its absence, it can. Now if the pattern of membership exhibited by the two sets is the same, then it seems reasonable to say that they are equal: they have done all that can be expected of them, as sets, to be regarded as identical. We are therefore led to the following principle.

Axiom of extensionality (strong form). If two sets have isomorphic $\in$-graphs, then they are equal.

(The $\in$-graph of a set is the membership relation restricted to the set, its members, their members, and so on.) As we have already noted, this assertion is provable in ZF, but in ZF^- (ZF without foundation) we need to add it as an axiom. It ensures, for instance, that there is at most one set Ω such that $\Omega = \{\Omega\}$ (since any two such sets would have to have isomorphic $\in$-graphs). However, it does not guarantee that there *is* such a set. Aczel (1988) and others have studied the consequences of adding to ZF^- not only the strong extensionality axiom just mentioned (which is essentially limitative) but also a permissive axiom generating non-well-founded sets (which

can be thought of as limit points in much the same way that irrational numbers are limits of rational numbers). The most natural of the axioms that have been studied is the following *anti-foundation axiom*:

Every graph is the $\in$-graph of some set.

7 Quine's systems

Another, more radical strand in attempts to resolve the set-theoretic paradoxes (see Paradoxes of set and property) is represented by the various forms of the theory of types (see Theory of types). We cannot, in any of the systems we have been describing so far, collect together all the objects to form another object, but we can certainly quantify over them; in the theory of types we cannot. Objects are stratified into 'types', which are not cumulative but otherwise resemble the levels of Scott's theory; variables are labelled with superscripts to indicate the type they range over. The formula $x^m \in y^n$ is taken to be well-formed only if $n = m + 1$. Now type theory is not, according to the strict definition adopted here, a form of set theory, because it does not have the axiom of extensionality. What it has instead is a schema of axioms, one for each type:

$$\forall x^{n+1} \forall y^{n+1} (\forall z^n (z^n \in x^{n+1} \leftrightarrow z \in y^{n+1}) \\ \rightarrow x^{n+1} = y^{n+1}).$$

Not to call this the axiom of extensionality may seem a pedantic cavil, particularly if the device of 'typical ambiguity' is introduced, whereby formulas are written with superscripts omitted and taken to stand schematically for any way of adding superscripts which produces a grammatical result. Thus the extensionality schema above is usually represented

$$\forall x \forall y (\forall z (z \in x \leftrightarrow z \in y) \rightarrow x = y).$$

Nevertheless, we maintain, this is not the axiom of extensionality. Typical ambiguity is not true generality. To see the difference, consider the formula $\exists y \forall x\ x \in y$: taken as typically ambiguous this stands schematically for such formulas as

$$\exists y^{n+1} \forall x^n\ x^n \in y^{n+1}$$

and is therefore true; taken as a formula in its own right it is false. The restrictions on what can be said in the theory of types have struck many writers as too severe. However, the means by which the theory avoids paradox are as secure as those of iterative set theories. Quine has proposed a system which uses type theory's method of paradox-avoidance but abandons its grammatical restrictions. Specifically, he regards formulas as genuine, not typically ambiguous, but calls a formula 'stratified' if it is possible to decorate it with superscripts so as to make it well-formed according to the theory of types. The system, which is known as NF because it was proposed in an article called 'New Foundations for Mathematical Logic' (1937), has the following axioms.

Axiom of extensionality: As before.

Axiom schema of stratified comprehension. If $\Phi(x)$ is any stratified formula in which y does not occur free then this is an axiom:

$$\exists y \forall x (x \in y \leftrightarrow \Phi(x)).$$

NF is very different from ZF. For one thing NF is finitely axiomatizable. Moreover, since the formula $x = x$ is stratified, it follows at once that there is a set of all sets: if we denote it $\mathbf{V}$ then $\mathbf{V} \in \mathbf{V}$. The axiom of choice is provably false in NF. When we come to arithmetic, it is possible in a natural way to define zero and the successor operation in NF, and then to define the set of natural numbers to be the intersection of all sets containing zero and closed under successors. This works well up to a point, but gives us mathematical induction only for stratified formulas. Unfortunately some useful formulas are not stratified. For example, we cannot prove in NF, and are therefore forced to add as an axiom, the *axiom of counting*:

If n is a natural number then it has exactly n predecessors.

In an effort to overcome this inconvenience Quine has proposed a second system called ML which stands to NF in somewhat the same relation that NBG stands to ZF. The second system takes $\mathbf{V}$ as a primitive constant and has the following axioms.

Axiom of extensionality: As before.

Axiom schema of class existence. If $\Phi(x)$ is a formula in which y does not occur free then this is an axiom:

$$\exists y \forall x(x \in y \leftrightarrow y \in \mathbf{V} \wedge \Phi(x)).$$

Axiom schema of set existence. If $\Phi(x, v_1, v_2, \ldots, v_n)$ is a stratified formula in which no variables other than those listed occur free, then this is an axiom:

$$\forall v_1, v_2, \ldots, v_n \exists y \in \mathbf{V} \\ \forall x(x \in y \leftrightarrow \Phi^{(\mathbf{V})}(x, v_1, \ldots, v_n)).$$

In contrast to NF, ML is not finitely axiomatizable if it is consistent. If Φ is any formula in which $\mathbf{V}$ does not occur then

$$\mathrm{NF} \vdash \Phi \text{ if and only if } \mathrm{ML} \vdash \Phi^{(\mathbf{V})}.$$

Thus ML is consistent if and only if NF is consistent. However, it is still not known whether ML and NF are consistent if ZF is consistent. If we define the natural numbers in superficially the same way as in NF, we get mathematical induction even for non-stratifiable formulas, obviating the need for an axiom of counting. However, this time we cannot prove that the class of natural numbers is a set (if ML is consistent). So now we have to add *this* as an axiom. Thus neither NF nor ML suffices without supplementation as a basis for mathematics.

Sextus Empiricus (*fl. c.* AD 200)

Sextus Empiricus is our major surviving source for Greek scepticism. Three works of his survive: a general sceptical handbook (Outlines of Pyrrhonism), a partly lost longer treatment of the same material, and a series of self-contained essays questioning the utility of the individual liberal arts.

Little is known about the life of Sextus Empiricus, our major source for Pyrrhonism. He was a doctor of the Empirical school, a sceptically-minded medical sect (see Hellenistic Medical Epistemology), and wrote some (lost) medical treatises. He also wrote three treatises on scepticism. *Outlines of Pyrrhonism*, is a three-volume handbook of sceptical arguments. The first covers the nature of Pyrrhonism and its distinction from other philosophies, the proper interpretation of the sceptic’s characteristic expressions (see Pyrrhonism §§3, 6), and the general form of sceptical argument (see Pyrrhonism §2). The second deals with the Pyrrhonian attack on dogmatic logic and epistemology, in particular with the issue of the criterion, and the nature of signs and proof (see Pyrrhonism §4). The third is on physics, attacking dogmatic notions of cause, motion, generation, space and time, number, and so on (see Pyrrhonism §5), and ethics (see Pyrrhonism §2).

A fuller treatment of the same material is standardly known as Books VII-XI of *Against the Professors* (sometimes called *Against the Mathematicians*). These break down into three subsections: *Against the Logicians* (Books VII-VIII), *Against the Physicists* (Books IX-X) and *Against the Ethicists* (Book XI), which contain the material to be found in Books II and III of *Outlines of Pyrrhonism*, as well as a reworking of some of the contents of *Outlines of Pyrrhonism* I 210-41. As Janáček (1963) has shown, *Against the Professors* VII-XI is incomplete, lacking at least one preliminary book corresponding to the bulk of Book I of *Outlines of Pyrrhonism*.

Finally, Sextus composed a series of treatises against the dogmatists’ conceptions of the liberal arts (grammar, rhetoric, geometry, arithmetic, astrology and music: *Against the Professors* I-VI), the scepticism of which seems a good deal more moderate in tone, and whose arguments owe much to Epicureanism.

Sextus makes no claims to originality as a thinker, and he clearly owes a great deal to Aenesidemus, and to subsequent Pyrrhonist systematizers, especially Agrippa. However, the Pyrrhonism he outlines is clear, consistent and rigorous; and, while the quality of the argumentation it contains is, as Sextus himself admits (*Outlines of Pyrrhonism* III 280), uneven, the Sextan version of scepticism became canonical. Diogenes Laertius (IX 116) mentions him as a prominent Pyrrhonian; and in the fourth century St Gregory of Nazianzus excoriates him in the same breath as Pyrrho himself, as the originator of ‘the vile and malignant disease’ of scepticism (*Orations* XII 21).

In 1564, Henri Étienne (better known as ‘Stephanus’) published a Latin translation of *Outlines of Pyrrhonism*; it was read with eagerness by Montaigne, and the ghost of Sextan argument can often be discerned behind Montaigne’s elegant and discursive prose. More importantly still, Greek scepticism came by this route to influence Descartes, and to provide the ultimate stimulus for his search for an epistemological foundation of knowledge and science proof against sceptical assault; as such, Sextus has had, albeit indirectly, a profound impact on the development of modern philosophy.

Sexuality, philosophy of

The philosophy of sexuality, like the philosophy of science, art or law, is the study of the concepts and propositions surrounding its central protagonist, in this case 'sex'. Its practitioners focus on conceptual, metaphysical and normative questions.

Conceptual *philosophy of sex analyses the notions of sexual desire, sexual activity and sexual pleasure. What makes a feeling a sexual sensation? Manipulation of and feelings in the genitals are not necessary, since other body parts yield sexual pleasure. What makes an act sexual? A touch on the arm might be a friendly pat, an assault, or sex; physical properties alone do not distinguish them. What is the conceptual link between sexual pleasure and sexual activity? Neither the intention to produce sexual pleasure nor the actual experience of pleasure seems necessary for an act to be sexual. Other conceptual questions have to do not with what makes an act sexual, but with what makes it the type of sexual act it is. How should 'rape' be defined? What the conceptual differences are, if any, between obtaining sex through physical force and obtaining it by offering money is an interesting and important issue.*

Metaphysical *philosophy of sex discusses ontological and epistemological matters: the place of sexuality in human nature; the relationships among sexuality, emotion and cognition; the meaning of sexuality for the person, the species, the cosmos. What is sex all about, anyway? That sexual desire is a hormone-driven instinct implanted by a god or nature acting in the service of the species, and that it has a profound spiritual dimension, are two - not necessarily incompatible - views. Perhaps the significance of sexuality is little different from that of eating, breathing and defecating; maybe, or in addition, sexuality is partially constitutive of moral personality.*

Normative *philosophy of sex explores the perennial questions of sexual ethics. In what circumstances is it morally permissible to engage in sexual activity or experience sexual pleasure? With whom? For what purpose? With which body parts? For how long? The historically central answers come from Thomist natural law, Kantian deontology, and utilitarianism. Normative philosophy of sex also addresses legal, social and political issues. Should society steer people in the direction of heterosexuality, marriage, family? May the law regulate sexual conduct by prohibiting prostitution or homosexuality? Normative philosophy of sex includes nonethical value questions as well. What is good sex? What is its contribution to the good life?*

The breadth of the philosophy of sex is shown by the variety of topics it investigates: abortion, contraception, acquaintance rape, pornography, sexual harassment, and objectification, to name a few. The philosophy of sex begins with a picture of a privileged pattern of relationship, in which two adult heterosexuals love each other, are faithful to each other within a formal marriage, and look forward to procreation and family. Philosophy of sex, as the Socratic scrutiny of our sexual practices, beliefs and concepts, challenges this privileged pattern by exploring the virtues, and not only the vices, of adultery, prostitution, homosexuality, group sex, bestiality, masturbation, sadomasochism, incest, paedophilia and casual sex with anonymous strangers. Doing so provides the same illumination about sex that is provided when the philosophies of science, art and law probe the privileged pictures of their own domains.

1 Conceptual analysis

The philosophy of sex investigates conceptual, metaphysical and normative questions, although the boundaries between these three are hardly firm. Metaphysical and normative philosophy of sex are well developed, stretching back to Plato and Augustine (see Plato §12); sexual ethics has a famous history, and the contemplation of the place of sexuality in human nature is central to Christianity. The analysis of sexual concepts, by contrast, is in its infancy. The subjects of analysis are these core concepts and the logical relationships among them: sexual desire, sensation, pleasure, act, arousal and satisfaction. Derivative sexual concepts, which presuppose an understanding of the core concepts, are also the subject of analysis. Among these are rape, sexual harassment, sexual orientation, sexual perversion, prostitution and pornography (see Pornography).

Consider adultery. It can be defined as a sexual act that occurs between two persons, at least one of whom is married but not to the other. The definition should also mention, as a necessary condition, willing and knowledgeable consent. Suppose *X* coerces *Y*, who is married to *Z*, into coitus. *Y* did not commit adultery, because

Y did not have the proper frame of mind; *Y* never intended to commit adultery or engage in intercourse at all. Or suppose *X* and *Y* engage in coitus, both believing, on the basis of good evidence (but falsely), that *X*'s spouse *Z* died years ago; or the unmarried *X* has good reason to think (but falsely, due to *Y*'s deception) that *Y*, too, is not married. Has *X* committed an adulterous sexual act, unwittingly and so, perhaps, not culpably; or is *X*'s lack of *mens rea*, *X*'s ignorance of the true state of affairs, incompatible with adultery?

We cannot fully understand the derivative sexual concept 'adultery' until we have defined 'sexual act'. If *X* and *Y* send to each other sexually arousing messages through the Internet, have they engaged in a sexual act ('cybersex')? Is their exchange of messages sexual enough, quantitatively or qualitatively, to be adulterous, if one of them is married? Here we can see the intertwining of conceptual and moral matters. A lack of clarity about 'sexual act' allows the exoneration of adultery by a convenient redescription of what occurs between *X* and *Y* - it was only 'fooling around', not 'real' sex. Another, quite opposite, manoeuvre, is possible. Theologians often define adultery in the spirit of Matthew 5: 28, making a sexual fantasy sufficient, even in the absence of physical contact: *X* commits adultery if *X* thinks lustful thoughts about *Y*.

2 Sexual activity

Our interest in defining 'sexual act' is not merely philosophical; it is also practical. Precise definitions of 'sexual act' are needed for social scientific studies of sexual behaviour and orientation (to be used in the consideration of questions about, for example, who engages in homosexual acts and whether this correlates with genetics, and how often people engage in sex) and for legislation in the areas of child abuse, rape, harassment and adultery.

Sexual acts might be defined as those involving sexual body parts. The sexual parts of the body are first catalogued; acts are sexual if and only if they involve contact with one of these parts. 'Sexual act', on this view, is logically dependent on 'sexual part'. But do we clearly understand 'sexual part'? Two people might shake hands briefly, without the act being sexual; they could, alternatively, warmly press their hands together and feel a surge of sexual pleasure. Sometimes, then, the hands are used nonsexually and sometimes they are used sexually. Are the hands a sexual part? Whether the hands are a sexual part depends on the activity in which they are engaged. Hence, instead of an act's being sexual because it involves a sexual body part, a body part is sexual because of the sexual nature of the act in which it is used. We might say that a genital examination is not a sexual act even though the genitals are touched; hence contact with a sexual part is not sufficient for an act to be sexual. But we could also say that not even the genitals are sexual parts in the requisite sense; for in the medical context the genitals are not being treated as sexual parts.

The morality of sexuality has been understood by some in terms of its procreative function (see §5). Alternatively, the procreative nature of sexual activity might be employed analytically rather than normatively. Sexual acts, on this view, are those having procreative potential in virtue of their biological structure. The principal case of such an act is heterosexual intercourse. This analysis, then, is too narrow, if taken as stating a necessary condition. Here is a more plausible formulation: sexual acts are (1) acts that are procreative in structure and (2) any acts that are the physiological or psychological precursors or concomitants of acts that are sexual by (1). This version casts a wider net, but not wide enough. Masturbation, which is not a procreative act and not often a precursor or concomitant of coitus, turns out not to be a sexual act. Another emendation suggests itself: sexual acts are also (3) acts that bear a close physical resemblance to the acts judged sexual by (1) or (2). This vague condition does not save the proposed analysis. Some sexual perversions (such as fondling shoes) are sexual even though they bear no reasonable resemblance to coitus or its concomitants. This analysis also suggests that homosexual acts, all of which are nonprocreative, are sexual just because they sufficiently resemble heterosexual acts. That seems to be the wrong reason for the right conclusion.

Another view is that both homosexual and heterosexual acts are sexual in virtue of the type of pleasure or sensation they produce. Thus it seems reasonable to propose that sexual acts are those that produce sexual pleasure (Gray 1978). But if pleasure is the criterion of the sexual, pleasure cannot be the gauge of the nonmoral quality of sex acts. The couple who have lost sexual interest in each other, and who engage in routine coitus from which they derive no pleasure, are still performing a sexual act. We are forbidden, by this analysis, from saying that they engage in sex but that it is (nonmorally) bad sex. Rather, we can say, at most, that they tried to engage in sex, and failed. Furthermore, in this analysis 'sexual act' is logically dependent on 'sexual pleasure', so we cannot say that sexual pleasure is the pleasure produced by sexual acts. Then how might we distinguish sexual pleasure or

sensations from others? This problem also arises for a more complex analysis: sexual acts are those acts that tend to satisfy sexual desire, where sexual desire is taken to be the desire for the pleasure of physical contact (Goldman 1977). ‘Pleasures of physical contact’ might not specify sexual pleasure accurately enough. An additional complication is that a gender difference in the experience and conceptualization of sexual pleasure might exist. Additionally, someone might experience sexual desire yet have no idea what to do as a result of having it, no idea that physical contact, or what kind of physical contact, is the next, but hardly mandatory, step. Sexual desire, as argued by Jerome Shaffer (1978: 186-7), might not be a desire *for* something or *that* something at all. What, then, are the features of a desire that make it sexual? Sexual desire is distinguished, on Shaffer’s account, by being accompanied by sexual excitement and arousal. We can, in turn, ask what sexual excitement and arousal are, as opposed to other kinds of excitement and arousal. For Shaffer, sexual arousal is ‘directly sexual in that it involves the sexual parts, viz., the genital areas’. Have we gone full circle?

Finally, sexual acts might be understood as those involving a sexual intention. But an intention to produce or experience sexual pleasure, for example, might be neither necessary nor sufficient for an act to be sexual. A couple engaging in coitus, both parties intending only that fertilization occur and neither concerned with sexual pleasure, performs a sexual act. Maybe this is not the correct sexual intention. But the intention to procreate is not it: gays and lesbians experience desire and arousal and engage in sex without any procreative intent. Furthermore, intentions are arguably irrelevant in making sexual acts sexual. Rape can be sexual whether the rapist intends to get sexual pleasure from it, to humiliate his victim, or to assert his masculinity. From the fact that in some rapes, rapists intend to degrade their victims, to dominate and exert power over them, it does not follow that the act is not sexual. Indeed, the rapist might have chosen a sexual act quite on purpose as his method to humiliate and degrade. His victim is degraded exactly by the sexual nature of the act endured; the victim experiences a shame that accompanies a forced sexual act but would not accompany sexless assault.

3 Social constructionism

What, then, are sexual acts? Maybe they have no transcultural or ahistorical essence, and the analytic project is doomed. Acts involving the same body parts are sometimes sexual, sometimes not. Some touches and movements are deemed sexual in one culture but not in others; the fragrances, mannerisms and costumes that are sexually arousing vary among places and times. No lowest common denominator exists that makes all sexual acts sexual. Bodily movements acquire meaning - as sexual, or as something else - by existing within a culture that attaches meaning to them. There are, then, only variable social definitions of the sexual.

Such is the view known as social constructionism (or anti-essentialism). As one proponent puts it, ‘the very meaning and content of sexual arousal’ varies so much among genders, classes, and cultures that ‘there is *no* abstract and universal category of "the erotic" or "the sexual" applicable without change to *all* societies’ (Padgug 1979: 54; original emphasis). Nancy Hartsock elaborates:

> We should understand sexuality not as an essence or set of properties defining an individual, nor as a set of drives and needs (especially genital) of an individual. Rather, we should understand sexuality as culturally and historically defined and constructed. Anything can become eroticized.
>
> (1983: 156)

Hartsock’s expression ‘anything can become eroticized’ must mean ‘anything can be linked to sexual arousal and pleasure’. That might be true; after all, unusual items bring paraphiliacs sexual joy. If so, however, there seems to be a common denominator after all, an essential even if narrow core to the sexual: an unchanging, culturally invariable subjective experience of sexual pleasure.

The history of sexuality is the history of our discourse about sex, as Michel Foucault might have put it. We create things by using words. There really is no such thing as masturbatory insanity or nymphomania - no medical condition, no psychological character trait, no underlying pathology. Well, there is, but only because we have picked out some behavioural patterns and made up a word to name them, not because masturbatory insanity and nymphomania have, like the moon, an existence independent of our words, our observations, and our evaluations of it. Social facts, such as the existence of ‘peasants’, ‘witches’ and ‘yuppies’ (Edward Stein’s examples), have an odd, plastic, fuzzy nature. Similar considerations apply to ‘perversion’, ‘philanderer’ and ‘homosexuality’. Thus the title of David Halperin’s social constructionist monograph, *One Hundred Years of Homosexuality* (1990). It did

not exist before the word 'homosexual' was coined by Károly Mária Benkert in 1869.

Adrienne Rich asserts that even heterosexuality is a 'man-made institution'. Heterosexuality is 'forcibly and subliminally imposed on women', 'designed to keep [them] within a male sexual purlieu' (1986: 34-57). Ti-Grace Atkinson similarly claims that 'sexual intercourse is a political construct, reified into an institution' (1974: 13). People have been engaging in sexual intercourse because doing so serves not their own individual needs, but a political purpose: to keep the species (and the system) going by replenishing the population. People have been groomed by society to perform the act of intercourse, their desire-pleasure apparatus manipulated, even created, to serve this purpose. Hence, when the development of brave-new-world reproductive technology eliminates the social function of coitus, individuals' 'sexual "drives" and "needs" would disappear' as well (20), there not being any reason to keep the grooming in operation. The end of biological reproduction is also the end of sex, or at least of sex as we know it. Whether that possible state would be a cause for celebration or despair is unclear.

4 The metaphysics of sex

In sex we are vulnerable to another's enticing words and seductive touch. Our wills are weak, so we are dominated as much by our desires as by the other's physical strength or alluring beauty. Engulfment or invasion of our bodies by the other's gaze and flesh is hazardous. In exchange for exquisite pleasure, we make ourselves susceptible to embarrassment, anguish, betrayal (see Vulnerability and finitude §2). This psychology of sex provides reason for taking sex, and so sexual ethics, seriously. Its consequences - transmission of disease, the existence of a new human being - do so as well. If procreation is a couple's contribution to God's ongoing work of creation, if it is the sacred ground where humans and God engage in a shared project, then sexuality must be protected by stringent ethics. Or if sexual personality resides at the core of moral personality, if the training of sexuality impinges on developing character in such a way that the failure to learn to control the pursuit of sexual pleasure undermines the achievement of virtue, then the moral education of the body is crucial.

In light of sexuality's intricate psychology and far-reaching consequences, sexual activity might be justifiable only by weighty nonsexual considerations. Consider the hostility of Christianity to sex, as in Augustine's *De nuptiis et concupiscentia (On Marriage and Concupiscence)*, where we hear the strains of Plato's *Phaedrus*:

> A man turns to good use the evil of concupiscence…when he bridles and restrains its rage…and never relaxes his hold upon it except when intent on offspring, and then controls and applies it to the carnal generation of children…not to the subjection of the spirit to the flesh in a sordid servitude.
>
> (I 9)

Neither is Immanuel Kant kind to sexuality: 'Sexual love makes of the loved person an Object of appetite…. Taken by itself it is a degradation of human nature' (1780-81: 163). If sexual desire objectifies, in virtue of pushing us to seek pleasure without regard for our partners, if sexual urges engender deception and manipulation, then sexuality is morally suspicious. Only special circumstances could make acting on these desires morally right. For these gloomy reasons, many conservative and religious thinkers, but also some feminists, believe that sexual activity is redeemed only by love or marriage.

In contrast, sexual liberals suppose that sexuality is a wholesome bonding mechanism that allows persons to overcome the psychological and moral tension between egoism and benevolence (see Egoism and altruism). Sexual activity involves pleasing the self and the other at the same time; these exchanges of pleasure generate gratitude and affection. Further, sexual pleasure is a valuable thing in its own right, the pursuit of which does not require external or nonsexual justification. And sexuality is a cardinal affirmation of the goodness of bodily existence. There is no contradiction in presuming that a virtuous person can lead a life in which sexual pleasure is sought for its own sake - in moderation, of course. Weak, not stringent, moral rules apply to sex.

The claim that sexual pleasure is valuable does not mean we should not condemn sexual misconduct. We often do, however, pardon sexually motivated misconduct when we would not excuse similar conduct motivated otherwise (see Pausanias in Plato's *Symposium* 182e-183c). Does sex warrant this exculpation? If the most intense way we relate to another person is sexually, then maybe forgiveness for sexual offences should be graciously forthcoming. But sexuality is hardly unique in the depth of the personal relationship it elicits; think about mutual hatred. Nor is there much intensity in the dull coitus of a long-married couple. According to another line of thought, sexuality has

a peculiar ability to thwart reason: sexual impulses make us temporarily deranged (recall the dark horse of Plato's *Phaedrus*). We are to be excused because in sexual matters we cannot control ourselves. But the lures of politics, ambition and money are just as powerful and devilish as the anticipations of the flesh. In none of these respects does sexuality seem unique or significant enough to deserve special attention.

Perhaps sexual desire - as a component of love and as opposed to mere 'horniness' - latches on to particular objects (I want *Jennifer*), in a way hunger does not (I want a sausage, and any fat, juicy one will do). Genuine *eros* makes us desire a particular person; crude desire is satisfiable by fungible bodies. But the distinction between *eros* and lust is a fine one, and in many instances doubtful; we only deceive ourselves that this person is not replaceable by others in our affections. As Roger Scruton puts it, 'a metaphysical illusion resid[es] in the heart of sexual desire' (1986: 95). Sexual passion misleads us; it makes it *appear* that we are ontologically more than we are, transcendental selves rather than mere material beings (1986: 130).

Plato, in the *Symposium*, also issued a warning: what we think we are seeking is not really what we want; our *eros* for bodies is really *eros* for truth and beauty. Augustine similarly thought that the search for God was hidden beneath the search for sensual pleasure in another's body. And for Arthur Schopenhauer, the beauty of the object of sexual desire was nature's way of tricking us (men?) into thinking that the satisfaction of our erotic love for our beloveds is for our own individual good. To the contrary, sexual love benefits only the species, for the good of which nature makes mere use of us (1844: 538-40) (see Schopenhauer, A. §4). This naturalist vision of sex is not far removed from Atkinson's anti-essentialism; both see its purpose in terms of the species and not of the individual.

5 Aquinas and natural law

For Aquinas, sexual acts are morally wrong in two different ways (*Summa theologiae* IIaIIae.154.1) (for an introduction to his ethical views, see Aquinas, T. §13). First, 'when the act of its nature is incompatible with the purpose of the sex-act [procreation]. In so far as generation is blocked, we have unnatural vice, which is any complete sex-act from which of its nature generation cannot follow.' Aquinas gives four examples (IIaIIae.154.11) of sexual acts that are unnatural vice because not procreative: 'the sin of self-abuse', 'intercourse with a thing of another species', acts 'with a person of the same sex', and acts in which 'the natural style of intercourse is not observed, as regards the proper organ or according to other rather beastly and monstrous techniques'. Second, 'the conflict with right reason may arise from the nature of the act with respect to the other party', as in incest, rape, seduction and adultery.

Sexual sins in the first category are the worst: 'unnatural vice flouts nature by transgressing its basic principles of sexuality, [so] it is in this matter the gravest of sins' (IIaIIae.154.12). Aquinas is replying to an interlocutor who argues that unnatural vice is *not* the morally worst sex. 'The more a sin is against charity', says the interlocutor, 'the worse it is. Now adultery and seduction and rape harms our neighbour, whereas unnatural lust injures nobody else, and accordingly is not the worst form of lust.' Aquinas rejects this thinking. Seduction, rape and adultery violate only 'the developed plan of living according to reason' that derives from humans living in society, while 'unnatural sins', which violate the plan of creation, are an 'affront to God'. If some sexual acts are unnatural, they are morally wrong, in Thomistic ethics, just for that reason. To the list of reasons sexual acts might be wrong - they are dishonest, cruel, unfair, manipulative, coercive, exploitative, selfish or negligently dangerous - a Thomist adds 'unnatural'. Not so the sexual libertarian. Mutual consent is, in the absence of third-party harm, sufficient for the morality of sexual acts, and no law of God or nature need supplement this basic principle of proper relations among humans.

In arguing that sexual behaviour ought to conform to human nature within God's plan, one must be able to justify particular conceptions of that nature and his intentions. Augustine and Aquinas knew, or thought they did, that God wanted sexuality to be the mechanism of procreation. Aquinas displays confidence in his account of human nature:

> It is evident that the bringing up of a human child requires the care of a mother who nurses him, and much more the care of a father, under whose guidance and guardianship his earthly needs are supplied and his character developed. Therefore indiscriminate intercourse is against human nature. The union of one man with one woman is postulated, and with her he remains, not for a little while, but for a long period, or even for a

whole lifetime.

(IIaIIae.154.2)

Christine Gudorf (1994), however, argues for a new, non-Augustinian yet Christian understanding of the body. Basing her view in part on the existence of the clitoris, an organ that on her view has only a pleasure-producing function and no procreative function, Gudorf argues that God designed the human body foremost for sexual pleasure.

Although he appeals to biology and not the Lord's plan, Michael Levin concludes, in agreement with Aquinas, that homosexual acts 'involve the use of the genitals for what they aren't for' (1984: 253). Homosexual anal intercourse is unnatural because being inside another man's rectum is not what a man's penis is 'for'; it is for penetrating a woman's vagina. This kind of Thomism is susceptible to mockery (Does a man's masturbation misuse the penis, or the hand? Does heterosexual cunnilingus misuse the tongue?) but it has also received serious discussion (see Murphy 1987). In deriving ethical judgments directly from nature, the problem is to come up with a coherent, plausible account of the 'natural'. Whereas Aquinas claims that a man's 'indiscriminate intercourse is against human nature', much recent biology claims that promiscuity in men is perfectly natural, the result of evolutionary mechanisms. In this way, science has the power to turn philosophical or theological reliance on nature on its head (see Evolution and ethics §§2-3). Thus, if the current research suggesting that homosexual orientation has a substantial genetic basis is vindicated, the Western religions might have to concede that such sexual desires and behaviour are, after all, part of the design of nature. Patricia Jung and Ralph Smith (1993) offer a Christian defence of loving, homosexual marriages, in part based on the idea that being homosexual is little different from being left-handed.

6 Kant's sexual ethics

Most philosophers have had something to say about sex; with a little digging, one can uncover the unsystematic sexual thoughts of Aristotle, Descartes and Hume. Others - such as Schopenhauer, Kierkegaard and Sartre - took sexuality more seriously. And for some, most notably Plato and Freud, the sexual was nearly the heart and soul. But in Kant's sexual philosophy, the conceptual, the metaphysical and the ethical are most provocatively combined; and in Kant, contemporary philosophical problems and disputes about sex can be glimpsed clearly.

Aquinas' fame (or notoriety) rests with his natural law sexual ethics; Kant is important as the author of a sexual ethics of respect (see Respect for persons). For Kant, human sexual interaction involves one person's merely using another for the sake of pleasure:

> there is no way in which a human being can be made an Object of indulgence for another except through sexual impulse…. Sexual love makes of the loved person an Object of appetite…. Sexual love…by itself and for itself…is nothing more than appetite…. As an Object of appetite for another a person becomes a thing and can be treated and used as such by every one. This is the only case in which a human being is designed by nature as the Object of another's enjoyment.

(1780-81: 163)

If all sexual acts - not only rape, or those in which consent is absent - are objectifying and instrumental, is not celibacy required? Kant thinks not. Following Paul ('The wife hath not power of her own body, but the husband: and likewise also the husband hath not power of his own body, but the wife', 1 Corinthians 7: 4), Kant lays down a stringent rule:

> The sole condition on which we are free to make use of our sexual desire depends upon the right to dispose over the person as a whole…. If I have the right over the whole person, I have also the right…to use that person's *organa sexualia* for the satisfaction of sexual desire. But how am I to obtain these rights over the whole person? Only by giving that person the same rights over the whole of myself. This happens only in marriage. Matrimony is an agreement between two persons by which they grant each other equal reciprocal rights, each of them undertaking to surrender the whole of their person to the other with a complete right of disposal over it…. If I yield myself completely to another and obtain the person of the other in return, I win myself back…. In this way the two persons become a unity of will…. Thus sexuality leads to a union of human beings, and in that union alone its exercise is possible.

(1780-81: 166-7)

Mary Ann Gardell, instead of sensing the Pauline ‘marriage debt’ in the Kantian exchange of rights, reads Kant as benignly claiming that ‘marriage transforms an otherwise manipulative masturbatory relationship into one that is essentially altruistic in character’ (1987: 11). But Kant speaks of marriage as a contract, an exchange of rights of access to the body. So he might be claiming that the marital pledge, the voluntary assumption of the terms of an agreement, assures that the spouses are not treating each other only as means, but also as ends, in the marriage bed. Or Kant might be justifying marital sex by abolishing the mere possibility of instrumentality: after the ontological union of two persons into one by marriage, there cannot *be* any use of one person by another (Baker and Elliston 1984: 26-7). This is why Kierkegaard found such views not benign but pernicious. ‘All pleasure is selfish. The pleasure of the lover…is not selfish with respect to the loved one, but in union they are both absolutely selfish, inasmuch as in union and in love they constitute one self’ (1845: 56).

Kant’s idea that marriage cleanses sex of instrumentality apparently implies that homosexual marriage would similarly cleanse same-sex sexuality. Kant sidesteps this conclusion, asserting that homosexuality is one of the *crimina carnis contra naturam*:

> Onanism…is abuse of the sexual faculty…. By it man sets aside his person and degrades himself below the level of animals…. Intercourse between *sexus homogenii*…too is contrary to the ends of humanity; for the end of humanity in respect of sexuality is to preserve the species without debasing the person.
>
> (1780-81: 170)

The homosexual ‘no longer deserves to be a person’. Kant, following Augustine and Aquinas, condemns nonprocreative sex as unnatural, even if it is, in his own sense, noninstrumental.

Kant’s notion of marriage, in which a person obtains rights over a person and their genitals, might itself reduce the spouses to sex objects, unless the voluntary agreement of the spouses to the arrangement is sufficient to eliminate mere use. But if we emphasize the voluntary nature of the exchange of rights that occurs in marriage, Kant’s contention that sex is permissible only in marriage is undermined, because two people - gay or straight - can grant each other reciprocal rights to dispose over their persons for a limited period of time (as in the casual sex of one evening). Nothing in the idea of an exchange of rights seems to entail that the exchange must be forever or exclusive. Is there something irreversible about *this* exchange of rights? If not, Kant’s defence of monogamous, lifelong marriage in terms of a ‘unity of will’ is no more convincing than Aquinas’ appeal to human nature.

7 Contemporary Kantians

From the various strands of Kant’s sexual philosophy, twentieth-century sexual conservatives and liberals have fashioned their own brands of Kantian sexual ethics.

Libertarian sexual ethics. If oral and anal sex, gay and lesbian sex, bisexual and group sex, contraceptive coitus, wearing lingerie and cosmetics, adultery, prostitution, making or viewing pornography, and the paraphilias - the things often condemned by conservative sexual ethics - can be carried out without harm befalling the participants or others, by consenting adults who know what they want, how could they be morally wrong? According to libertarian sexual ethics, as long as the persons involved are participating voluntarily, they are not merely using each other for their own purposes; the free and informed consent of each to the acts that occur is sufficient to eliminate mere use and thus to make sexual activity, of whatever flavour, morally permissible (see Libertarianism). The paradigmatically wrong sexual act is not buggery, but rape, in which the absence of consent makes the mere use obvious. Consensual participation in sexual activity implies that each person is respecting the other as an autonomous agent capable of making up their mind about the value of the activity. Furthermore, as Alan Goldman claims, sexual partners, by recognizing each other’s ‘subjectivity’, can satisfy Kant’s ‘second formulation’:

> Even in an act which by its nature ‘objectifies’ the other, one recognizes a partner as a subject with demands and desires by yielding to those desires, by allowing oneself to be a sexual object as well, by giving pleasure or ensuring that the pleasures of the act are mutual.
>
> (1977: 87)

It follows that neither marriage nor heterosexuality nor love are necessary for salvaging sex, and the acquisition of

the right of bodily access can be temporary and reversible.

The Vatican. Although the Church embraces natural law ethics, it has also invoked Kant. In his 1968 encyclical 'Humanae Vitae', Paul VI argued against the permissibility of the use of contraceptive devices. 'Each and every marriage act…must remain open to the transmission of life' (sect. 11), and therefore 'conjugal acts made intentionally infecund' (sect. 14) are immoral. In Kantian style, he warned that the use of contraceptive devices makes husbands 'lose respect' for their wives. Since using contraception implies the act is primarily for pleasure, the husband sees his wife as 'a mere instrument of selfish enjoyment' (sect. 17). Karol Wojtyla (later John Paul II) has expressed a similar thought:

> When the idea that 'I may become a father'/'I may become a mother' is totally rejected in the mind and will of husband and wife nothing is left of the marital relationship, objectively speaking, except mere sexual enjoyment. One person becomes an object of use for another person.
>
> (1960: 239)

Rejecting the libertarian view that consent is sufficient, John Paul also asserted that only love eliminates the sexual use of one person by another, since love is a unification of persons achieved through the mutual gift - rather than a Kantian contractual exchange - of their selves. Marriage might by its nature be indissoluble (irreversible) if, once a person makes a gift of self to another, that gift cannot, for logical reasons, be taken back or returned.

Conservative sexual philosophy. John Finnis (1993: 12) argues that there are morally worthless sexual acts in which 'one's body is treated as instrumental for the securing of the experiential satisfaction of the conscious self'. In masturbating or in being sodomized, the body is just a tool of satisfaction and, as a result, one undergoes 'disintegration'. 'One's choosing self [becomes] the quasi-slave of the experiencing self which is demanding gratification.' As in Kant, the worthlessness and disintegration attaching to masturbation and sodomy attach to 'all extramarital sexual gratification'. This is because only in married, heterosexual coitus do 'their reproductive organs…make them a biological (and therefore a personal) unit'. Finnis begins with the Kantian intuition that sexual activity involves treating the body instrumentally, and he concludes with the Kantian intuition that sex in marriage avoids disintegrity since the couple is a unit: 'the orgasmic union of the reproductive organs of husband and wife really unites them biologically'.

8 Consent and coercion

Sexual activity between an adult and a child - 'intergenerational' sex - is considered morally wrong in many cultures. The arguments against it claim that it is physically and psychologically harmful to the child and violates canons of consent. Children are not able to consent to sex in the same way they are not able to consent to surgery, or to what school they attend; in these areas parents are empowered to decide for them. Defenders of intergenerational sex reply that depending on the age of the child and the acts performed, sex is not physically harmful, and it is psychologically harmful only to the extent that society condemns it. In addition, children are able to consent to sex in the same way they are able to give consent, or withhold it, to what they eat, wear, or the films they see. Thus whether children are able to give meaningful consent to sex depends on its significance - whether sex is more like eating pizza or contributing to the 'grand design'. (Analogous views are possible about sex between humans and animals: Is it harmful to the nonhuman creatures? Can they consent? Does it matter?) Intergenerational sex thus suggests separate and pressing issues about the nature of consent.

In the 1920s, Bertrand Russell admonished: 'the intrusion of the economic motive into sex is always…disastrous. Sexual relations should be a mutual delight, entered into solely from the spontaneous impulse of both parties.' In employing this principle, Russell found prostitution lacking. He also observed, prophetically, that it applied elsewhere, to married women who have economic reasons for acquiescing to the sexual demands of their husbands (1929: 121-2; see Engels 1884). Russell was voicing something close to Robin Morgan's feminist definition of rape:

> How many millions of times have women had sex 'willingly' with men they didn't want to have sex with? … How many times have women wished just to sleep instead or read or watch the Late Show? … Most of the decently married bedrooms across America are settings for nightly rape.
>
> (1977: 166)

The fundamental idea is that genuinely consensual participation in sex, without a hint of coercion, requires substantial economic, social and psychological equality between the persons involved. A society characterized by both poverty and wealth is one in which people are exposed to economic coercion, even if it appears that they freely consent to what they do. If some groups have less economic and social power than others, their members will be exposed to sexual coercion, among other kinds. Women's consent to heterosexual sexual activity might be largely chimerical also in virtue of systematic male dominance. If women's consent to heterosexual acts within an oppressive patriarchal society is not genuine, this will be especially true of prostitution, which can be seen as rape perpetrated by men employing economic or psychological power rather than physical assault or the threat of a knife.

An extreme view is that the presence of any pressure is coercive and morally objectionable. In 'Nonviolent Sexual Coercion' (1991), Charlene Muehlenhard and Jennifer Schrag list, among other things, 'status coercion' (women are coerced into sex or marriage by a man's occupation) and 'discrimination against lesbians' (which compels women into sexual relationships with men) as objectionable forms of coercion. Depending on the kind of case we have in mind, it might be more accurate to say either that some pressures are not coercive (a husband who constantly nags for sex) or that some pressures are coercive but not morally objectionable (a woman who marries for economic reasons). This last point might hold as well for sexual objectification: is it all wrong? Why is sexual objectification condemned, when other objectification is not?

Other questions about consent to sex are analogous to those that arise in medicine, business and law (see Medical ethics, §3). How *specific* must consent be in order that a person engage voluntarily in subsequent sexual behaviour? Because consenting is opaque, when one person agrees 'to have sex' with another, the first has not necessarily consented to any sensual caress or coital position the second has in mind. How *explicit* must consent be in order to be an indication of voluntary choice? Whether consent can be implied reliably by nonverbal behaviour, and whether anyone should take nonverbal cues as showing decisively that another has consented to sex, are questions that arise in discussions of acquaintance rape. And how *informed* must consent be? Do sexual partners have a duty to reveal their marital or immunological status? Conventional wisdom thinks so, but there is dissent (see Mayo 1996).

9 Utilitarianism

It seems likely that the John Stuart Mill who wrote *On Liberty* would have defended libertarian sexual ethics on general utilitarian grounds, insisting that the consent of the participating parties is morally sufficient as long as significant harm to third parties is avoided (see Utilitarianism). Do as you will in your experiments in living, he might have said; neither the law nor public opinion should be brought to bear unless, say, violations of assignable duties occur. Kantians and Thomists agree that the interests of third parties and society might be adversely affected by sexual activity, even if the sexual act occurring between two persons embodies genuine respect for each or is fully natural.

The difficult question concerns which of the ubiquitous effects on third parties or society are significantly harmful. Is a person harmed by becoming nauseous when noticing two homosexuals (or heterosexuals) kiss in public? Is a spouse harmed by the infidelity about which he or she knows nothing? Is someone harmed merely by knowing that immoral or offensive conduct is occurring? This area of social philosophy has been especially contentious, since decisions about 'harm' have profound implications. A narrow notion of harm yields a permissive (sexual and nonsexual) ethics and provides little justification for using the criminal law to interfere with sexual behaviour; a broad notion of harm implies the opposite. Mill and James Fitzjames Stephen squared off against each other over this issue in the nineteenth century; in the twentieth century, the debate was revived, initially by Patrick Devlin and H.L.A. Hart (see Law and morality §§1-3; Law, limits of). Utilitarian sexual ethics can in any event be restrictive *or* permissive, depending on the truth of empirical assertions about the consequences of sexual behaviour, or about the consequences of trying to prevent it. In addition to depending on contestable notions of wellbeing, the empirical claims underlying utilitarian judgments are difficult to verify. Similar problems plague claims that the existence of pornography helps maintain a social environment inimical to the wellbeing of women (see Pornography).

10 Sadomasochism and love

Sadomasochism has long been scorned by moralists. Nonlibertarian Kantians think that sadomasochistic sexual activity is wrong because it violates the personhood of the participants; humiliating and demeaning attitudes retain their character even when the sexual acts are consensual. A utilitarian might conclude that this activity, or legally permitting it, does more harm than good (as in some utilitarian arguments against permitting active euthanasia). And for a moral paternalist, it is wrong for one person to harm another, even if the latter is willing, or for persons to allow themselves to be harmed. For other utilitarians and Kantians, however, sadomasochism can be engaged in lovingly, or while fully respecting one's sexual partner, and without significant harm being done to nonparticipants.

Sadomasochism has been gaining in visibility, especially in homosexual culture. The radical libertarian sons of Kant have even given birth to the daughters of de Sade. Thus the debate over sadomasochism is especially heated among feminists, for whom there are strong partisan differences in the moral and political assessment of both heterosexual and homosexual sadomasochism (see Feminist ethics §3). About lesbian sadomasochism in particular, Claudia Card says, on the positive side, that its 'participants generally wish each other well and respect each other's choices'. But Card also worries about such activities: 'the only things distinguishing the behavior of [a top] from battery and other abuse may be the motivations of the parties and the consent of the [bottom]' (1995: 221) - and, for Card, neither the consent nor the motivation (for example, sexual pleasure) seem to turn battery and abuse into anything other or better than battery and abuse. But what more could we want in distinguishing respectful sadomasochism from battery, other than the consent to experience mutual pleasure? To say that consent is not enough, that the persons must be married, committed to each other, 'in love', or must avoid uncommonly repugnant acts, is to jeopardize all unconventional sex, not just sadomasochism. The task for a defender of this position is to deny that marriage is essential for legitimate sexuality and to bless a great deal of human sexual interaction on the basis of consent (such as homosexuality), without adopting a libertarianism so thin that it condones sadomasochism. There are well-founded doubts that that project can be successfully completed.

Unwoolly accounts of the ingredient that is required beyond consent are hard to come by, but the idea that something is required has often recommended itself:

> Avoiding deceit and coercion are only the core of treating others as persons in sexual relationships. In avoiding these we avoid…obvious ways of using as (mere) means. But to treat another as a person in an intimate, and especially an intimate sexual, relationship requires far more. These further requirements reflect the intimacy rather than the specifically sexual character of a relationship. However, if sexual relationships cannot easily be merely relationships between consenting adults, further requirements for treating another as a person are likely to arise in any sexual relationship. Intimate bodies cannot easily have separate lives.
>
> (O'Neill 1985: 269-70)

If the quest for sexual pleasure threatens the self's wholeness (Finnis), the other's personhood (John Paul II), and society's viability (Devlin), if it insults the human spirit (Augustine), the natural order of things, and God (Aquinas), then love - be it a dose of *agapē* or *caritas* (an uplifting sort of *eros*), or the trendy 'intimacy' - is necessary, and perhaps (as in some versions of romanticism) also sufficient, for sexual relations to be licit.

The thought that love is the magical ingredient has immediate application to homosexuality: gay and lesbian sex can be justified within loving, monogamous homosexual marriages. Whether sadomasochism can genuinely express or involve love seems to be an empirical question, as long as we have a workable operational definition of 'love'. What kind of domestic arrangement do these sex partners have - is it much different, aside from the sadomasochistic sex, from Ozzie and Harriet's? Furthermore, love as the extra ingredient makes defending the use of contraception easy: sex acts, including the nonprocreative, express and bolster the love spouses have for each other. Given these rhetorical benefits, it might not be surprising that natural science cements the link between sex and love: 'Nature has emotionally enriched the human reproductive impulse through love, and in doing so she has immensely increased our enjoyment of both' (Walsh 1994: 371). In one biological swoop, a perplexing question has been answered, namely, 'why species survival, the means of impregnation, and emotional/erotic relationships should ever have become so rigidly identified with each other' (Rich 1986: 35; see Hume 1739/40: section 11). If you prefer God to nature, try Paul VI's answer: there is an 'inseparable connection, established by God, which man on his own initiative may not break, between the unitive significance and the procreative significance which are both inherent to the marriage act' (1968: §12).

References and further reading

The most challenging items on this list are the books by Boswell, Foucault, Halperin, Hartsock, MacKinnon, Price and Scruton, plus some of the essays in the collections edited by Murphy, Soble, Stein and Stewart.

Aquinas, T. (1266-73) *Summa theologiae (Synopsis of Theology)*, ed. T. Gilby, Cambridge: Blackfriars, 1968, vol. 43, IIaIIae.153-4.(Classic natural law sexual ethics.)

Atkinson, T-G. (1974) *Amazon Odyssey*, New York: Links.(A famous piece of radical feminism that condemns the political 'institution' of heterosexuality.)

Augustine (419-21) *De nuptiis et concupiscentia (On Marriage and Concupiscence)*, in *Works*, vol. 12, Edinburgh: T. & T. Clark, 1874.(Early Christian sexual ethics and metaphysics: concupiscence is sinful; sexual intercourse is forgiven in marriage; children thereby produced contract original sin. See also *The City of God* [vols 1-2] and *Confessions* [vol. 14].)

Baker, R. and Elliston, F. (eds) (1975) *Philosophy and Sex*, B uffalo, NY: Prometheus Books; 2nd edn, 1984, editorial introduction, 11-36.(Introductory textbook, which includes papers on marriage, abortion, contraception, pornography, homosexuality and paedophilia, and contains an enormous bibliography compiled by W. Vitek.)

Boswell, J. (1980) *Christianity, Social Tolerance and Homosexuality*, Chicago, IL: University of Chicago Press. (A book of history rich in intelligent philosophical discussion of the definition of homosexuality, social constructionism, and Aquinas' natural law.)

Card, C. (1995) *Lesbian Choices*, New York: Columbia University Press.(Discusses lesbian ethics, culture, friendship and sexuality.)

Davis, M. (1983) *Smut: Erotic Reality/Obscene Ideology*, Chicago, IL: University of Chicago Press.(Insightfully divides the metaphysical terrain into Jehovanist, Naturalist and Gnostic philosophies of sex.)

Engels, F. (1884) *Der Ursprung der Familie, des Privateigentums und des Staats*, trans. *The Origin of the Family, Private Property and the State*, New York: International Publishers, 1972.(The Marxist alternative to Augustine's theory of original sin.)

Finnis, J.M. (1994) 'Law, Morality, and "Sexual Orientation"', *Notre Dame Law Review* 69 (5): 1049-76.(Lays out a Catholic case against the toleration of homosexuality by the law; criticizes M. Nussbaum's understanding of Greek homosexuality. Occasionally woolly.)

Finnis, J.M. and Nussbaum, M. (1993) 'Is Homosexual Conduct Wrong? A Philosophical Exchange', *The New Republic* 15 November: 12-13.(Finnis presents a Kantian-Catholic argument for the moral inferiority of homosexuality; Nussbaum finds the argument unconvincing.)

Foucault, M. (1978, 1985, 1986) *The History of Sexuality*, vol. 1, *An Introduction*, New York: Vintage Books; vol. 2, *The Use of Pleasure*, New York: Pantheon; vol. 3, *The Care of the Self*, New York: Vintage Books. (Provocative ruminations on sexuality and its history by the purported instigator of the academic furore over social constructionism.)

Gardell, M.A. (1987) 'Sexual Ethics: Some Perspectives From the History of Philosophy', in E.E. Shelp (ed.) *Sexuality and Medicine*, Dordrecht: D. Reidel, vol. 2, 3-15.(A brief introduction to the history of sexual ethics.)

Goldman, A. (1977) 'Plain Sex', *Philosophy and Public Affairs* 6 (3): 267-87; repr. in A. Soble (ed.) *The Philosophy of Sex*, Savage, MD, Rowman and Littlefield, 2nd edn, 1991, 73-92.(This straightforward, sensible paper combines conceptual analysis of 'sexual activity' and 'sexual desire' with Kantian, libertarian sexual ethics.)

Gray, R. (1978) 'Sex and Sexual Perversion', *Journal of Philosophy* 75 (4): 189-99; repr. in A. Soble (ed.) *The Philosophy of Sex*, Totowa, NJ: Rowman and Littlefield, 1980, 158-68.(Conceptual analysis of 'sexual perversion' and 'sexual act'.)

Gudorf, C.E. (1994) *Body, Sex and Pleasure: Reconstructing Christian Sexual Ethics*, Cleveland: Pilgrim Press. (Sexual pleasure is a gift from God; the fundamental ethical principle governing sexual relations is 'mutuality'.)

MacKinnon, C.A. (1989) *Toward a Feminist Theory of the State*, Cambridge, MA: Harvard University Press.(The ‘unmodified feminist’ legal and social analysis of heterosexuality, rape and pornography.)
Mayo, D.J. (1997) ‘An Obligation to Warn of HIV Infection?’, in A. Soble (ed.) *Sex, Love and Friendship*, Amsterdam: Editions Rodopi, 447-53.(Argues that HIV-positive persons do not have a moral duty to warn sexual partners of the health hazards of contemplated sexual acts.)
Morgan, R. (1977) *Going Too Far: The Personal Chronicle of a Feminist*, New York: Random House.(Her collected *oeuvre*; includes ‘Theory and Practice: Pornography and Rape’.)
Muehlenhard, C.L. and Schrag, J.L. (1991) ‘Nonviolent Sexual Coercion’, in A. Parrot and L. Bechhofer (eds) *Acquaintance Rape: The Hidden Crime*, New York: John Wiley, 115-28.(A catalogue of ways women are [or might be] coerced into sexual activity without being forced violently.)
Murphy, T.F. (1987) ‘Homosexuality and Nature: Happiness and the Law at Stake’, *Journal of Applied Philosophy* 4 (2): 195-204.(A thorough critique of M. Levin’s ‘Why Homosexuality is Abnormal’; the essay focuses on the arguments from nature and happiness and rebuts their purported legal implications.)
Murphy, T.F. (ed.) (1994) *Gay Ethics: Controversies in Outing, Civil Rights and Sexual Science*, New York: Haworth Press.(Introductory-to-advanced collection of essays on such issues as outing, gay marriage, gays in the military, affirmative action, and the science of sexual orientation.)
Nagel, T. (1969) ‘Sexual Perversion’, *Journal of Philosophy* 66 (1): 5-17; revised version repr. in *Mortal Questions*, Cambridge: Cambridge University Press, 1979, 39-52.(Sophisticated analysis of ‘sexual perversion’ that draws on Sartre and Grice in formulating an account of natural human sexual psychology.)
Noonan, J.T. (1965) *Contraception: A History of Its Treatment by the Catholic Theologians and Canonists*, Cambridge, MA: Harvard University Press, enlarged edn, 1986.(Excellent history of the philosophical and theological arguments surrounding the use of methods to prevent conception during heterosexual intercourse.)
Nussbaum, M. (1995) ‘Objectification’, *Philosophy & Public Affairs* 24 (4): 249-91.(Analyses seven distinct types of sexual objectification; some are benign, others malignant. Occasionally pornographic.)
O’Neill, O. (1985) ‘Between Consenting Adults’, *Philosophy & Public Affairs* 14 (3): 252-77.(An essay on what it is - and what it is not - to treat someone as a person, with respect; the account is applied to sexual relations.)
Padgug, R. (1979) ‘Sexual Matters: On Conceptualizing Sexuality in History’, *Radical History Review* 20 (Spring/Summer): 3-23; repr. in E. Stein (ed.) *Forms of Desire*, New York: Routledge, 2nd edn, 1992, 43-67. (Social constructionism with a Marxist gloss: hunger is hunger, but not all hunger is the same, as Marx put it in the *Grundrisse*.)
Paul VI (1968) ‘Humanae Vitae’, *Catholic Mind* 66 (September): 35-48; repr. in R. Baker and F. Elliston (eds) *Philosophy and Sex*, Buffalo, NY: Prometheus Books, 2nd edn, 1984, 167-83.(This papal encyclical is Paul VI’s post-Vatican II affirmation of the doctrine that the use of contraception is morally illicit.)
Pineau, L. (1989) ‘Date Rape: A Feminist Analysis’, *Law and Philosophy* 8: 217-43.(A lucid discussion of what it is for one person to have a *reasonable belief* that another person has consented to engage in sexual activity.)

Plato (*c*.386-380 BC) *Symposium*, trans. R. Waterfield, Oxford: Oxford University Press, 1994.(Plato's brilliant, moving, sometimes hilarious, and endlessly discussable account of *eros*.)

Price, A.W. (1989) *Love and Friendship in Plato and Aristotle*, Oxford: Clarendon Press.(Of the vast writings on love, sex and friendship in Plato and Aristotle, this absorbing treatise is one of the best places to start.)

Primoratz, I. (1993) 'What's Wrong With Prostitution?' *Philosophy* 68 (264): 159-82.(The answer according to this essay is 'Not much'. An uncompromising libertarian view of prostitution, which rebuts feminist objections.)

Rich, A. (1986) 'Compulsory Heterosexuality and Lesbian Existence', in *Blood, Bread and Poetry*, New York: W.W. Norton, 23-75.(A classic item of radical feminist sexual philosophy.)

Ruse, M. (1988) *Homosexuality: A Philosophical Inquiry*, New York: Blackwell.(A comprehensive philosophical treatment of ethical and scientific questions about homosexuality.)

Russell, B.A.W. (1929) *Marriage and Morals*, London: Allen & Unwin.(A little book of liberal common sense that caused Russell untold trouble.)

SAMOIS (ed.) (1981) *Coming to Power*, Palo Alto, CA: Up Press; 2nd edn, Boston, MA: Alyson Publications, 1982.(A brave collection of essays defending lesbian sadomasochism; especially noteworthy is G. Rubin's 'The Leather Menace'. *SAMOIS* is the name of a lesbian/feminist sado-masochism collective.)

Schopenhauer, A. (1844) *Die Welt als Wille und Vorstellung*, vol. 2, Leipzig: Brockhaus; trans. E.F.J. Payne, *The World as Will and Representation*, vol. 2, Indian Hills, CO: Falcon's Wing Press, 1958.('The Metaphysics of Sexual Love' appears as ch. 44 in the supplements to book 4. A cynical - or just hard-nosed - naturalistic view of human sexuality in which we are mere pawns in a larger game and our personal dreams and intentions are illusions.)

Scruton, R. (1986) *Sexual Desire: A Moral Philosophy of the Erotic*, New York: Free Press.(A conservative theory of sex thick with Kantian themes; Scruton's favourite notion is 'individualising intentionality' (see 384). Readers are also recommended to see M. Nussbaum's tart review of this essay, 'Sex in the Head', *New York Review of Books*, 18 December 1986, 49-52.)

Shaffer, J. (1978) 'Sexual Desire', *Journal of Philosophy* 75 (4): 175-89; repr. in A. Soble (ed.) *Sex, Love and Friendship*, Amsterdam: Editions Rodopi, 1997, 1-12.(Sophisticated conceptual analysis of 'sexual desire'; a gem of an example of what the philosophy of sex - or philosophy - can be.)

Singer, I. (1984-7) *The Nature of Love*, Chicago, IL: University of Chicago Press, 3 vols.(A magnificent history of the philosophy of love and sex, from Plato right through twentieth-century psychology.)

Soble, A. (ed.) (1980) *The Philosophy of Sex*, Totowa, NJ: Rowman and Littlefield; 2nd edn, Savage, MD: Rowman and Littlefield, 1991.(Introductory-to-advanced textbook; topics covered in the 2nd edn include pornography, adultery, prostitution, rape, homosexuality, sadomasochism and perversion.)

Soble, A. (ed.) (1989) *Eros, Agapē and Philia*, New York: Paragon House.(Introductory-to-advanced textbook, a mixture of historical [Plato, Aristotle, Montaigne, Descartes, Pascal] and contemporary pieces [G. Vlastos, L. Kosman, D. Hamlyn, S. Mendus, W. Newton-Smith].)

Soble, A. (1996) *Sexual Investigations*, New York: New York University Press.(A work of sexual ethics, politics and conceptual analysis.)

Soble, A. (ed.) (1997) *Sex, Love and Friendship*, Amsterdam: Editions Rodopi.(Introductory-to-advanced collection of sixty contemporary essays that discuss Plato, Aristotle, Spinoza, Kant, Sade, Kierkegaard, Heidegger, and diverse topics, including sexual objectification, abortion, sexual perversion, love and sex, pornography and gay rights.)

Stein, E. (ed.) (1990) *Forms of Desire*, New York: Garland; 2nd edn, New York: Routledge, 1992.(Advanced collection of essays explaining, defending and criticizing social constructionism.)

Stewart, R.M. (ed.) (1995) *Philosophical Perspectives on Sex and Love*, New York: Oxford University Press. (Comprehensive advanced textbook on sex, love [of various kinds] and friendship; sexual topics discussed include pornography, prostitution, sexual objectification, perversion, homosexuality, sadomasochism, rape and adultery.)

Sullivan, A. (1995) *Virtually Normal: An Argument About Homosexuality*, New York: Alfred A. Knopf.(An iconoclastic neoconservative political philosophy applied to questions revolving around homosexuality; Sullivan argues that the linchpin of gay liberation is access to civil marriage.)

Vannoy, R.C. (1980) *Sex Without Love: A Philosophical Exploration*, Buffalo, NY: Prometheus Books.(Argues that sexual activity is morally and nonmorally sound without being attached to love; provides conceptual analyses of 'sexual perversion' and 'love'.)

Verene, D. (ed.) (1972) *Sexual Love and Western Morality*, New York: Harper & Row; 2nd edn, Boston, MA: Jones and Bartlett, 1995.(Introductory textbook; 2nd edn includes Plato, Aristotle, Augustine, Aquinas, Luther,

Kant, Schopenhauer, Nietzsche, Hegel, Sartre, Freud, Sade and Foucault.)

Walsh, A. (1994) 'Love and Sex', in V.L. Bullough and B. Bullough (eds) *Human Sexuality: An Encyclopedia*, New York: Garland, 369-73.(An introduction, with an evolutionary bent, to the relationship between love and sex.)

Weithman, P. (1997) 'Natural Law, Morality, and Sexual Complementarity', in D. Estlund and M. Nussbaum (eds) *Sex, Preference, and Family: Essays on Law and Nature*, New York: Oxford University Press, 227-46.(A meticulous explication, analysis and critique of John Finnis' sexual ethics.)

Wertheimer, A. (1996) 'Consent and Sexual Relations', *Legal Theory* 2 (1): 89-112.(Sharp, insightful conceptual analysis of the moral and legal force of 'consent' in, especially, sexual contexts.)

Willetts, *Love and Responsibility*, New York: Farrar, Strauss & Giroux, 1981.(A Kantian-Catholic sexual ethics, written before Wojtyla, a professor of philosophy, was elected pontiff; his *official* view is expressed in, for example, 'Evangelium Vitae', *Origins* 24 (42): 689-727, 1995.)

Shaftesbury, Third Earl of (Anthony Ashley Cooper) (1671-1713)

Shaftesbury, whose influence on eighteenth-century thought was enormous, was the last great representative of the Platonic tradition in England. He argued that by natural reason we can see that the world is an intelligible, harmonious system. In reflecting on our character traits we will inevitably approve of those which contribute to the good of humanity and of the whole system. These same personal qualities are also needed for a happy life, so virtue and happiness go hand in hand.

Shaftesbury is often seen as the founder of the moral sense or 'sentimentalist' school in ethics, whose members held that morality was based on human feeling rather than on reason. Although leading sentimentalists, such as Hutcheson and Hume, made use of many of his ideas, Shaftesbury himself has more in common with the rationalists, who held that there are eternal moral truths which we can know by the use of reason.

1 Life and influences

Anthony Ashley Cooper, Third Earl of Shaftesbury, was born in February 1671. Superintendence of his education was handed over to no less a personage than John Locke, with whom Shaftesbury seems to have had an ambivalent relationship. While honouring him as his 'friend and foster father', Shaftesbury came not only to reject, but even to detest, much of Locke's philosophy. He played a full part in English political life, first in the Commons and then in the Lords, though ill health forced occasional retreats to the Continent. He devoted the latter portion of his life to writing; his published work was eventually brought together in his three-volume *Characteristics of Men, Manners, Opinions, Times* (1711), a work very widely read in the eighteenth century.

Shaftesbury was deeply influenced by Greek and Roman thought, in which he distinguished two strands. The first presupposes that we live in an ordered and intelligible universe; the second that everything came into being by chance and that nothing has any meaning. It is to the former strand that Shaftesbury owes allegiance. It proceeds through Plato, Aristotle, the Neoplatonists and Platonized Christianity to the Cambridge Platonists of the seventeenth century (see Cambridge Platonism; Neoplatonism). Shaftesbury's notebooks reveal in particular the marked influence of the Stoics, especially Epictetus and Marcus Aurelius (see Stoicism).

2 Teleology

Shaftesbury's conception of the world is thoroughly teleological. By the use of unaided natural reason, we can come to see that the universe forms a well-ordered, intelligible, harmonious system, in which humans have their proper place. To understand the nature of anything, including ourselves, is to know what functions are natural and proper to it, and which ones are unnatural and perverted. This knowledge is practical as well as theoretical. In the Platonic tradition to which Shaftesbury belongs, to know the good is to love it. Shaftesbury is thus an apostle of intellectually disciplined enthusiasm; rational beings cannot help but be moved once they are aware of this universal harmony, which Shaftesbury celebrates in glowing and lyrical terms. To live in accordance with nature, to have one's inner harmony attuned to the outer, is to be both virtuous and happy. Virtue is its own reward; the virtuous life is in itself the most fulfilling there is.

The passions that disturb our lives stem from false values, from a wrong assessment of what is good and bad. Once we see that our good is to be found in the part we play in the good of the whole then we can face hardship and even death with equanimity. For we find our true good not in externals, such as wealth or reputation, which can be taken from us, but in a balanced and harmonious mind, which cannot be overthrown by anything except our folly. Moreover, the goods of the mind are superior to any goods we find in nature or in human art. As Shaftesbury explains in *The Moralists, A Philosophical Rhapsody* (1709), mind is not only the source of harmony, beauty and goodness (which for him are essentially one and the same), but is itself better and more beautiful than its products. To value any external good more highly than inner harmony is to prefer a secondary beauty to its primary source, to prefer the shadow to the reality.

Shaftesbury stresses the immanence of the divine mind rather than its transcendence. Shaftesbury often pictures God's relation to the world as more like that of the soul to the body than it is like that of the watchmaker to his watch. We see this in *The Moralists* (part III, section 1) where we find an unusual variant of the argument from design which starts from the issue of personal identity (see God, arguments for the existence of §§4-5). Among all

the changes to both body and mind which any person undergoes in the course of life, it is undeniable that there is something which unites these stages and makes them all properties of the same person. We cannot give a coherent account of the metaphysical status of this self, but that there is such a continuing self which governs and superintends one's life is undeniable. Since nature is also self-regulating and orderly, it too must be governed by a mind, which bears the same relation to the world and its activity as our mind does to our body and actions, even if we can give no clear indication of its metaphysical status.

In spite of his token orthodoxy Shaftesbury is a true parent of the Enlightenment in his willingness to question authority and in his advocacy of liberty. In thought and discussion there should be freedom of speech (at least among educated gentlemen!). No subject is too grave that it may not be subject to jest; for raillery, Shaftesbury contends, is a test of truth. Error cannot withstand mockery. Art and culture only flourish in conditions of freedom. Genuine patriotism can only spring from an identification with the body politic which cannot be found in tyrannies.

3 Ethics

The core of Shaftesbury's philosophy, however, is his moral theory, which is most fully and systematically expounded in his *Inquiry Concerning Virtue or Merit* (1699), his earliest work. In the first part he delineates what goodness and virtue are. Every creature, and every species, is part of a wider system to which it contributes. Each system is itself part of a wider system, until we reach the universe, the complete system which incorporates all the subsystems. Each individual (or species) is to be judged by its contribution to the good of its system and, ultimately, by its contribution to the good of the whole.

In judging an individual creature we are concerned with its character, with what Shaftesbury calls its affections - its, desires, motives and enjoyments. A good creature is one whose affections will, in the normal course of events, cause it to act in a way that will be for the good both of itself and of the system of which it is a part. While animals can be good or bad, humans alone can be virtuous or vicious, for humans alone are self-conscious and capable of reflecting on their own actions and affections so that these can in their turn become the object of an affection, this time of approval or disapproval. We are naturally and ineluctably led to approve of what is natural and honest and to disapprove of what is dishonest and corrupt. Our capacity for reflection, however, enables us to be self-governing, and thus virtuous or vicious, for we can choose whether to indulge our good or our bad inclinations (see Autonomy, ethical).

We might note that Shaftesbury departs from the Stoic model in one respect. For those in the Socratic tradition the four cardinal virtues are wisdom, courage, temperance and justice. Benevolence, pity or compassion receive less emphasis. Epictetus concedes that we should behave sympathetically towards the unfortunate; but we should not disturb our stoic tranquillity by pitying them. Shaftesbury, by contrast, puts the social virtues of love, friendship and universal benevolence at the forefront of his theory (see Virtues and vices §1).

Shaftesbury proceeds in the second half to ask what reason we have to be virtuous. He assumes without argument that the only reason we can offer is that it is in our interests - a virtuous life will be a happy one. He is thus a rational egoist, for he holds that questions of the rational justification of a way of life must appeal to self-interest. But he is not a psychological egoist, for he holds, as against Hobbes, that agents have altruistic as well as egoistic motives (see Hobbes, T. §8). Nor is he an ethical egoist, for morality requires us to be motivated by concern for others (see Egoism and altruism §1).

Shaftesbury then argues, ingeniously if not always persuasively, that the qualities of character needed to live a good life are the very same as those needed to live a virtuous one. In particular, proper development of the social affections, which are directed to the good of others, gives a degree and type of satisfaction not otherwise available.

It is customary to view Shaftesbury as the source or founder of the moral sense or sentimentalist school of ethics, whose foremost members were Hutcheson and Hume (see Moral sense theories). It is true that they were much influenced by him, but in the great eighteenth-century debate as to whether morality is founded on reason or on sentiment, Shaftesbury should, I think, be counted on the rationalist side in so far as he holds that there are eternal moral truths, existing independently of us, and revealed to us by the use of reason.

DAVID McNAUGHTON

List of works

Shaftesbury (1995) *The Shaftesbury Collection*, Bristol: Thoemmes, 4 vols. (Comprehensive recent collection.)

Shaftesbury (1699) *An Inquiry Concerning Virtue or Merit*, ed. D. Walford, Manchester: Manchester University Press, 1977. (In the first part of his major work on ethics Shaftesbury discusses what virtue is, and in the second part he argues that it is in our interest to be virtuous.)

Shaftesbury (1709) *The Moralists, A Philosophical Rhapsody*, in *Characteristics of Men, Manners, Opinions, Times*, vol. 2, ed. J.M. Robertson, London: Grant Richards, 1900; repr. in *The Shaftesbury Collection*, vol. 2, Bristol: Thoemmes, 1995. (A philosophical dialogue, in which the claim that the world is the product of an intelligent and beneficent Mind is examined and defended.)

Shaftesbury (1711) *Characteristics of Men, Manners, Opinions, Times*, ed. J.M. Robertson, London: Grant Richards, 1900, 2 vols; repr. in *The Shaftesbury Collection*, vols 1 and 2, Bristol: Thoemmes, 1995. (Contains all important works published by Shaftesbury in his lifetime.)

Shaftesbury (1900) *The Life, Unpublished Letters, and Philosophical Regimen of Anthony, Earl of Shaftesbury*, ed. B. Rand, London: Swan Sonnenschein; repr. in *The Shaftesbury Collection*, vol. 3, Bristol: Thoemmes, 1995. (Contains Shaftesbury's important personal notebooks and a fairly full selection of his letters.)

Shaftesbury (1914) *Second Characters, or The Language of Forms*, ed. B. Rand, Cambridge: Cambridge University Press; repr. in *The Shaftesbury Collection*, vol. 4, Bristol: Thoemmes, 1995. (Contains Shaftesbury's uncompleted proposed work on aesthetics, including his long and fascinating instructions to the artist on the composition of 'The Judgement of Hercules', which he commissioned while in Italy.)

Shah Wali Allah (Qutb al-Din Ahmad al-Rahim) (1703-62)

Shah Wali Allah of Delhi, the greatest Muslim scholar of eighteenth-century India, made an immense contribution to the intellectual, economic, social, political and religious life of the Muslim community in India, the effects of which persist to the present day. He lived during a time when the Muslim empire was losing ground on the Indian subcontinent, with the Muslim community divided and at odds. Seeking to give theological and metaphysical issues a new rational interpretation and labouring to harmonize reason and revelation, he tried to reconcile the various factions of the Indian Muslims, thereby protecting the empire from collapse.

Shah Wali Allah contended that the root cause of the downfall of the Indian Muslims was their ignorance of the sacred scripture of Islam. He initiated a movement with the theme 'Back to the Qur'an', and translated the Qur'an into Persian to facilitate its understanding among all the Muslims of India. It is believed to be the first complete translation of the Qur'an from the Arabic by an Indian Muslim scholar.

1 Life

Qutb al-Din Ahmad ibn 'Abd al-Rahim, known as Shah Wali Allah, was born in AH 1114/AD 1703 near Delhi, a member of a distinguished intellectual and religious family. He received a highly structured education and spiritual instruction at the *madrasa* (religious school) established by his father, Shah 'Abd al-Rahim, at Delhi. As well as the Qur'an, he studied Arabic and Persian grammar and literature and the higher philosophical, theological, metaphysical, mystical and juridical texts. He graduated from the school when he was barely fifteen years old; in the same year, his father initiated him into the famous Naqshbandi order. He began his career as a teacher at the Madrasa-e-Rahimiyya under the tutelage of his father; after the death of the latter in AH 1131/AD 1719, Shah Wali Allah became the head of the *madrasa*, teaching all the current sciences at the school for about twelve years. During the same period he continued his own studies, growing in stature as a teacher and attracting students to his circle.

In AH 1143/AD 1731, Shah Wali Allah went on the *hajj* (pilgrimage to Mecca), after which he remained in Mecca and Medina, the sacred cities of Islam, for about fourteen months, studying *hadith* (accounts of the Prophet) and engaging in intellectual discussions, meditation and spiritual perfection. During this time, he saw the forty-seven spiritual visions which form the subject matter of his famous mystical work *Fuyud al-haramayn (Emanations or Spiritual Visions of Mecca and Medina)*. After making his second *hajj*, Shah Wali Allah returned home to Delhi in AH 1144/AD 1732. He spent the rest of his life teaching *hadith* literature and metaphysics and writing. All but one or two of his works were produced during his later years. He died in AH 1176/AD 1762.

2 Intellectual and metaphysical contribution

Shah Wali Allah wrote in both Arabic and Persian. He published between fifty and seventy works, including five collections of letters and epistles. His writings played a major role in the intellectual and spiritual life of the Muslims in the Indo-Pakistan subcontinent, a role which continues today. Some of these works have greatly changed the Muslim approach to the study of the Qur'an.

In addition, Shah Wali Allah tried to reshape Islamic metaphysics in greater conformity with the teachings of the Qur'an and the *sunna* of the Prophet. He adopted a more rational approach to the controversial issues of metaphysics, which led to greater harmony among subsequent Islamic metaphysical thinkers. He was careful to give a balanced criticism of some of the views of his predecessors and contemporaries. His constructive and positive approach to those issues was always considered a sincere attempt at reconciliation.

Shah Wali Allah made the first attempt to reconcile the two (apparently) contradictory doctrines of *wahdat al-wujud* (unity of being) of Ibn al-'Arabi and *wahdat al-shuhud* (unity in conscience) of Shaykh Ahmad Sirhindi. Shaykh Muhyi al-Din ibn al- 'Arabi, the advocate of *wahdat al-wujud*, was of the opinion that being in reality is one and God. All other actual and possible beings in the universe are manifestations and states or modes of his Divine Names and Attributes. By the act of creation through the word *kun* (be), Ibn al-'Arabi means the descent of Absolute Existence into the determined beings through various stages. This gradual descent of the Absolute Existence is called *tanazzulat al-khamsa* (five descents) or *ta'ayyunat al-khamsa* (five determinations) in Sufi terminology. On the other hand, according to Shaykh Ahmad Sirhindi, the exponent of the doctrine of *wahdat*

al-shuhud, God and creation are not identical; rather, the latter is a shadow or reflection of the Divines Name and Attributes when they are reflected in the mirrors of their opposite non-beings (*a'dam al-mutaqabila*). Shah Wali Allah neatly resolved the conflict, calling these differences 'verbal controversies' which have come about because of ambiguous language. If we leave, he says, all the metaphors and similes used for the expression of ideas aside, the apparently opposite views of the two metaphysicians will agree. The positive result of Shah Wali Allah's reconciliatory efforts was twofold: it brought about harmony between the two opposing groups of metaphysicians, and it also legitimized the doctrine of *wahdat al-wujud* among the *mutakallimun* (theologians), who previously had not been ready to accept it.

Shah Wali Allah wrote about thirteen works on metaphysics, which contain his constructive and balanced metaphysical system. One of the most important is *al-Khayr al-kathir (The Abundant Good)*. This work is divided into ten chapters, each called a *khizana* (treasure). The first four chapters deal with the reality of *wujud* (being), knowledge of God, the relationship between God and the universe, and human knowledge. From the discussion of human knowledge, Shah Wali Allah turns to the discussion of the reality of prophecy and the prophethood of Muhammad. In the seventh *khizana*, he deals with the rules and principles of sainthood and mysticism. The eighth and ninth chapters contain details about practical aspects of Islam, the *shari'a*, as well as the eschatological view of Islam. In the tenth *khizana*, Shah Wali Allah explains his theological view which, according to him, is in full accord with Ash'arite theology.

Altaf al-quds fi ma'rifat lata'if al-nafs (The Sacred Knowledge) is another metaphysical work concerned with the inner dimensions of human personality. Here Shah Wali Allah deals with the important questions of mystical intuition (*kashf*) and inspiration (*ilham*). He examines systematically the reality of both the external and internal perceptive qualities of a human being as the heart, the intellect, the spirit, the self, the secret (*al-sirr*) and the ego. A separate chapter is devoted to the metaphysical teachings of Shaykh Junaid Baghdadi, wherein he presents a brief historical account of mysticism. The last chapter deals with the subtle question of 'thoughts and their causes'. Shah Wali Allah specifies various external and internal causes which affect the human mind and produce thoughts.

Sata'at (Manifestations) is a systematic division of *wujud* (being), representing Shah Wali Allah's view concerning the *tashkik al-wujud* (hierarchy or gradation of being). Existence, in relation to determined being, is composed of existence and essence and has many grades, stages and modes. The particular beings in the universe provide the foundation for the claim of the *tashkik* (gradation) and *kathrat* (multiplicity) of being. Each grade or stage covers a certain area of determination and each stage is related to the next, not in a way that a material being is connected to another material being, but in *ma'nawi* (conceptual) manner. He describes the relationship between the various stages of being as like that between the lights of various lamps in a single room. The lights of these lamps are apparently mingled and are one, and are difficult to differentiate from one another; but in reality, they are distinguishable from one another because of the number of the lamps.

Shah Wali Allah's 'magnum opus' is his *Hujjat Allah al-baligha (The Profound Evidence of Allah)*. This comprehensive work deals with both intellectual and practical aspects of Islam. The first part deals with metaphysics, scholastic theology, the gradual development or evolution of human society and the philosophy behind the divine injunctions. The second part is devoted to ethics, politics, rituals and the social life of Islam.

Al-Tafhimat al-ilahiyya (Instructions or Clear Understanding) is one of his most comprehensive metaphysical works. The work is divided into sections called *tafhim* (instruction). Both Arabic and Persian languages are used for the expression of ideas and concepts in this work. These *tafahim* (plural of *tafhim*) are actually Shah Wali Allah's mystical visions and experiences, and his letters and articles written to various people at various times in different contexts. The famous epistle called *Maktub al-madani (Madinian Epistle)* to Isma'il Afandi is a part of the second volume of the book. This article is a detailed description of *wahdat al-wujud* and *wahdat al-shuhud*, along with Shah Wali Allah's attempt at reconciliation concerning this controversial issue. In addition to the ontological discussions, the work also includes the author's cosmological, anthropological and theological views.

Another important metaphysical work is *al-Budur al-bazigha (The Full Moons Rising in Splendour)*. The introduction deals with basic metaphysical issues such as *wujud* in general, the unity of God, the essence and existence of God and the relationship between God and the universe. Shah Wali Allah considers the universe to be a manifestation of the Divine Attributes. In the first chapter, he deals with the study of humanity with respect to its social and rational being. The second chapter is devoted to humanity's relationship with the Creator. At the end of

the work, Shah Wali Allah describes in detail the reasons and causes for the development and evolution of the various *shara'i'* (religions or religious laws) and *milal* (religious communities).

Shah Wali Allah also tried to provide a basis for bringing the four schools of law closer to each other. His commentaries on the *Mu'atta* (a collection of the Prophet's sayings) of Imam Malik, called *al-Musawwa* (Arabic) and *al-Musaffa* (Persian), were written with a view to finding common orthodox ground for the reconciliation of different schools of Islamic law. Likewise, he wrote *'Aqd al-jid fi akham al-ijtihad wa'l-taqlid* with the proposal that the door of *ijtihad* (judgement) is open. According to him, the experts of Islamic knowledge (*'ulama'* (religious scholars) and*mujtahidin* (legists) have the right to respond effectively to new situations instead of being perpetually bound to previous solutions.

3 Political contribution

A hallmark of Shah Wali Allah was his ability to reconcile opposing points of view to the satisfaction of each side. Standing behind this aspect of his teachings is the unity of the Muslim community or *umma*. His powerful abilities as a reconciler enabled him to provide common ground and a strong basis for co-operation and harmony between the Sunni and Shi'i.

Shah Wali Allah lived during a time of political and moral decline, chaos and destruction in the Mughul empire. His vantage point near the centre of the Muslim state gave him a clear view of the situation. He did his best to bring stability to the tottering empire and protect the Indian Muslims from disaster. Through his writings, especially his letters, he appealed to the Muslim rulers, nobles and intelligentsia to be aware of the dreadful situation and its possible consequences. His correspondence reveals many factors of Indian politics in the eighteenth century. His detailed letter to Ahmad Shah Abdali, the founder and ruler of Afghanistan, contained a comprehensive picture of the political situation in India. Ahmad Shah Abdali heeded Shah Wali Allah's call to invade India and restore Muslim power to the country, culminating in the defeat of the Marathas and their allies at the battle of Panipat in 1761. Shah Wali Allah himself left a rich intellectual legacy in the form of literary works, well-trained disciples including his four sons - who also became eminent scholars - and one of the greatest educational institutions of the time.

Shao Yong (1012-77)

One of the founders of neo-Confucianism, Shao Yong was a Chinese philosopher best known for his use of numerical ideas to illustrate natural patterns of change. His thought encompassed a variety of concerns including knowledge, language and self-cultivation, and has received differing interpretations.

Shao Yong (styled Yaofu, called Kangjie) was considered one of the five founders of the Song dynasty (960-1279) philosophical movement called the learning of the Way, widely known as neo-Confucianism. His family was from north China, and he established his home in Loyang. While friendly with scholars and officials, Shao never took the examinations and declined several official recommendations. His major works were *Huangji jingshishu (Book of the Supreme Ultimate Ordering the World)* and *Yichuan jirangji (Collection of Yichuan's Beating on the Ground)*, a collection of poetry. His supposed authorship of *Yuqiao wendui (Conversation between the Fisherman and Woodcutter)* and *Wuming gongzhuan (Biography of Mr No Name)* has not been verified.

Combining aspects from different traditions, Shao focused on natural patterns of change in the universe and the experience of sagely knowledge. Called the 'Prior to Heaven learning', his ideas regarding universal regularities belonged to the learning of images and numbers, based on the *Yijing (Book of Changes)* and emphasizing correlations. His views on knowledge, language and self-cultivation drew on Daoist thinking (see Daoist philosophy). While accepting Confucian thought, Shao stressed that political history, individual behaviour and the natural universe shared identical patterns. Buddhist influence is suggested in his ideas on sagely perception (see Buddhist philosophy, Chinese).

Shao viewed the universe as characterized by constant change, occurring according to regular patterns. Composed of *qi* (matter-energy) (see Qi), the universe and cosmological development were described in terms of theoretical levels, from the extrasensory original unity to all the things/events of human experience. Although cycles of twelve and thirty were important, most critical were the binary and quaternary patterns of change. Original unity (the Supreme Ultimate) gives rise to *yin* and *yang* which in turn interact to produce divisions of four, eight (the trigrams) and eventually sixty-four (the hexagrams) (see Yijing; Yin-yang). Production and completion, and movement and response, illustrate the binary pattern while the four seasons, four directions and four classics illustrate the quaternary pattern.

Representable by numbers and images, patterns were unknowable without things, the two largest of which were the heavens and earth. Changes in one realm were correlated with those in the other, according to a quaternary pattern that systematically classified all things/events. For instance, the heavens were symbolized by three, five, seven, nine and the sun, moon, stars and celestial markers, while earth was symbolized by two, four, six, eight and water, fire, earth and stone. The relationships among the categories explained all kinds of activity, and numbers reflected the regularity of change.

Shao urged people to overcome their limited perspectives, but only a sage perceived things from the viewpoint of the whole. Admired as a principled Confucian recluse, eccentric, teacher and poet, Shao was respected for his numerological formulations, predictive abilities and ideas about the sage. Shao's numerical ideas have been misinterpreted as bad astronomy and as a deterministic view of human behaviour.

Shem Tov family

The ibn Shem Tov family included four Jewish intellectuals of fifteenth century Spain whose philosophical, theological, homiletical and polemical works followed the persecution of 1391 and the ensuing mass apostasy of Jews. Responding to these traumatic events, the Shem Tovs rethought the place of philosophy in traditional Judaism. Although the pater familias *reacted sharply to the spiritual crisis by criticizing Maimonides and endorsing Kabbalah, his offspring charted a more moderate course that enabled Jewish intellectuals to cultivate philosophy and the kindred arts and sciences while asserting the ultimate primacy of their revealed faith over philosophy, and its philosophical superiority to Christianity.*

1 Shem Tov ibn Shem Tov

Shem Tov ibn Shem Tov (*c.* 1380-1441) witnessed the destruction of Spanish Jewry in his youth. Like Hasdai Crescas and Shlomo Alami, he responded by comprehensively re-examining Judaeo-Hispanic culture. In *Sefer ha-'Emunot (The Book of Beliefs)* he held Jewish rationalists responsible for the mass defections that followed the persecutions. He charged his chief targets, Abraham ibn Ezra and Moses Maimonides, with denying cardinal tenets of rabbinic Judaism including divine retribution, bodily resurrection, personal providence, miracles and individual immortality. They had accorded Jewish Law merely instrumental value, had made human perfection dependent on knowledge of philosophy, equated prophecy with natural human knowledge and reduced the Torah to a popular allegory of philosophic profundities.

Shem Tov conceded to philosophy sound knowledge of the natural world, knowledge that can aid us in grasping the plain sense of the Torah, but he found philosophy inherently unreliable in metaphysics and subordinated it to revelation, whose salvific truths are beyond the ken of natural reason (see Revelation). Revelation itself requires authoritative interpretation through a tradition that, for Shem Tov, includes the teachings of Kabbalah (see Kabbalah). In a work still extant in manuscript on the subject of the Sefirot - originally Neo-Pythagorean hypostases but later understood to be aspects of the divine pleroma - he places Kabbalistic theosophy above philosophy.

Shem Tov's endorsement anticipated by over a century the rise of Kabbalah to centrality in Jewish theology, but he failed to diminish the stature of Maimonides or to discredit Judaeo-Hispanic rationalism. His own sons, Joseph (*c.*1400-*c.*1460) and Isaac (d. *c.*1489) and his grandson, Shem Tov ben Joseph (*fl.* 1480s), perpetuated Jewish Aristotelianism and defended Maimonides, although they agreed that philosophy cannot secure salvation alone; it must be perfected by revelation and tradition. They accepted Kabbalah as integral to Judaism but did not displace philosophy, instead incorporating Kabbalistic ideas into their rationalism. For example, they identified the Sefirot with the 'attributes of action' allowed to God in Maimonidean negative theology.

2 Joseph and Isaac ibn Shem Tov

Joseph, the most illustrious of the Shem Tovs, was a court physician and auditor of accounts in the courts of King John II and Henry IV of Castile until he was deposed in 1456. A prolific exegete, Joseph wrote commentaries, extant in manuscript, on Aristotle's *On the Soul* and *Nicomachaean Ethics*, Averroes' now lost epistle on the possibility of conjunction (in both longer and shorter formats), his epistle on the nature of material intellect, his commentary on Alexander of Aphrodisias' *On the Intellect*, and Moses Narboni's commentary on al-Ghazali's Avicennan summary, *Maqasid al-falasifa (The Intentions of the Philosophers)*. No longer extant are commentaries on Porphyry's *Isagōgē* and Aristotle's *Economics*. The surviving manuscripts show a deep familiarity with Judaeo-Muslim Aristotelianism and, strikingly, with Christian scholasticism.

Joseph's younger brother Isaac, a popular teacher of Aristotelian philosophy in Aguilar di Campaha, Castile, wrote four supercommentaries on Averroes's middle commentary on Aristotle's *Physics*, as well as treatments (now lost) of Averroes' long commentaries on *On the Soul* and *On Generation and Corruption* and on al-Ghazali's *Maqasid al-falasifa*. In the *Physics* supercommentaries, Isaac rebutted Crescas' attack on the twenty-five theses of Aristotelian philosophy which Maimonides had laid out as the premises of Aristotelian proofs of the existence, unity and incorporeality of God. Crescas' aim had been to liberate Judaism from Aristotelian philosophy. A loyal Maimonidean, Isaac dismissed Crescas' critique as ill-taught philosophy. He failed to grasp the originality and

subtlety of Crescas' views, but pondered the origin of the universe and other metaphysical questions in his lost *'Etz ha-Da'at (The Tree of Knowledge)*.

3 Shem Tov son of Joseph ibn Shem Tov

The last known member of the family, Shem Tov, son of Joseph ibn Shem Tov, also taught philosophy in commentaries. He wrote a supercommentary on Averroes' middle commentary on Aristotle's *Physics* and *On the Soul*, Hebrew philosophical works on the distinction between matter and form, and a work on teleology. The technical virtuosity of these works, written to preserve a worldview that had come under increasing attack, attests to the abiding appeal of philosophy in Spain until the very end of the Jewish presence there, but they show little novelty. Intellectually, the movement was a spent force. The real creativity of the Shem Tovs (and of other Jewish thinkers of their day) lay in theology and philosophical hermeneutics.

4 Theology, preaching, hermeneutics and polemics

The major vehicle of Jewish theology in fifteenth-century Spain was commentary on Maimonides' *Guide to the Perplexed* (see Maimonides, M.) Joseph ibn Shem Tov's commentary on the highly controversial 68th chapter of Part I survives in manuscript. Isaac commented on the entire *Guide* (the commentary on Part I is extant), and Joseph's son Shem Tov's linear commentary on the entire *Guide* is still printed in traditional editions. By seeking to fathom Maimonides' original intent, these commentaries ranged over the full repertoire of medieval Jewish philosophy, including God's existence and attributes, creation, providence, miracles, prophecy, human knowledge and the ultimate human goal. The works also defended Maimonides against charges of heresy and inconsistency. Like other Maimonideans (Abraham Shalom, Abraham Bibago and Moses Alashkar), the Shem Tovs ascribed their own moderate views to Maimonides and projected upon him a synthesis they had developed from their own Maimonidean reflections on Averroes (see Ibn Rushd), Avicenna (see Ibn Sina), al-Ghazali, Ibn Bajja and Ibn Tufayl.

Joseph ibn Shem Tov's systematic treatises develop his moderate synthesis of religion and philosophy. In *Kevod Elohim (The Glory of God)*, he follows Meir Alguades' Hebrew translation of the Latin *Nicomachaean Ethics*, seeking to harmonize Aristotle's idea of happiness with rabbinic values. Taking his cue from Thomas Aquinas, Joseph argues that Aristotle delineates the supreme temporal good, whereas eternal happiness can be known only through revelation. Like Aquinas, Joseph understood this ultimate felicity as a beatific vision by the immortal soul of God's essence; but only those who live by the precepts of the Torah can attain such eternal bliss. Joseph's narrowing of philosophical universality by the specification of this requirement clearly aimed to strengthen the faith of despairing Spanish Jews.

In his *Moznei ha-'Iyyun (The Scales of Speculation)*, Joseph developed these themes further and sought to explain the mass apostasy of Spanish Jews as the outcome not of philosophical study but of weak character and superficial intellectual commitment, which had allowed his countrymen to succumb to the material blandishments of Christianization. From Talmudic sources, he showed that there was no religious prohibition against philosophy, which was in fact highly beneficial in understanding of the revealed canon. Addressing another oft-cited cause of mass apostasy, Joseph composed *Da'at 'Elyon (Knowledge of the Supernal)* attacking the determinism of Abner of Burgos, a famous Jewish apostate and Christian theologian (see Voluntarism, Jewish §1). Finally, he wrote a commentary on Yeda'aiah Berdersi's *Behinat 'Olam (Examination of the Universe)*, a popular fourteenth-century poetic summary of Jewish Aristotelianism. These two works are no longer extant.

The Shem Tovs all engaged in sacred hermeneutics. The elder Shem Tov commented on Mishnah Avot and the Passover Haggadah; Joseph commented on Lamentations, Job and Genesis, and on Tractate *Ketubot* of the Babylonian Talmud. Shem Tov ben Joseph published homilies on the Torah based on his sermons. Preaching was the major vehicle for the dissemination of Jewish theology, and Joseph was not only a popular preacher (fifteen of his sermons survive in manuscript) but the author of the earliest known Hebrew manual on homiletics, *'Eyn ha-Qore (The Eye of the Reader)*. Inspired by a humanist concern for eloquence, it sought to improve the quality of Jewish preaching and counter the appeal its Christian counterpart.

Like other polemicists of his day, Joseph defended Judaism as a rational religion grounded in the revelation of God's perfect wisdom. Christianity was philosophically inferior, based on irrational beliefs and paradoxes. To aid

the resistance to conversionary pressures and rebut Christian claims to spiritual superiority, he translated Hasdai Crescas' *Bittul 'Iqqarey ha-Notzrim (Refutation of Christian Principles)* from the Catalan original into Hebrew and wrote a commentary that preserves the only extant version of this influential text (see Crescas, H.). He also commented on Profiat Duran's epistle *Al Tehi ka-Avotekha (Be Not like Your Fathers)*, known to Christians under the distorted title *Alteca Boteca*. Duran had mocked the apostasy of the epistle's addressee by satirizing Christian dogmas (see Duran, P.). Joseph's commentary sought to ensure that Jews understood the irony of the original polemical work, but it had the unintended effect of alerting the Inquisition to the work's genuine intent.

Shestov, Lev (Yehuda Leib Shvartsman) (1866-1938)

A major though atypical figure of the Russian Religious-Philosophical Renaissance, Shestov taught that reason and science can neither explain tragedy and suffering, nor answer the questions that matter most. A maximalist, a subjectivist and an anti-dogmatist, Shestov regarded philosophical idealism as an attempt to gloss over the 'horrors of life' and attacked morality and ethics as inherently coercive. He maintained that science ignores the contingent, the unique and the ineffable, that philosophy cannot be a science, and that necessity depersonalizes and dehumanizes the individual. Philosophy and revelation are incompatible because God is not bound by reason, nature or autonomous ethics. To God 'all things are possible', even undoing what has already happened. God even restored Job's dead children to him - the same children, not new ones, Shestov insisted.

In Dobro v uchenii gr. Tolstogo i Fr. Nitshe (The Good in the Teaching of Tolstoy and Nietzsche) (1900) and Dostoevskii i Nitshe(Dostoevsky and Nietzsche) (1903) Shestov attacked philosophical idealism and attributed his subjects' philosophies to a defining personal experience: Tolstoi's horror at urban poverty, Nietzsche's illness, and Dostoevskii's Siberian exile, respectively. These books established Shestov as a major literary critic and interpreter of Nietzsche. Around 1910 he turned to philosophy and religion. In his magnum opus Athènes et Jerusalem (1938) Shestov preached a religious existentialism centred on the living God of Abraham, Isaac and Jacob, and argued that evil came into the world with knowledge. Adam and Socrates were fallen men because they opted for knowledge over life and faith. Socrates, Aristotle, the Scholastics, Descartes, Spinoza, Kant, Hegel and Husserl were all faith-destroying. Shestov preferred the anti-rationalism of Dostoevskii, Nietzsche, Tertullian, Luther, Pascal and Kierkegaard. He wanted to restore the primordial freedom of Adam before the Fall. Although Shestov quoted the Gospels and certain Christian theologians approvingly, he was not a Christian. Neither was he an adherent of traditional Judaism.

A brilliant stylist, Shestov used reason and knowledge to combat reason and knowledge. He distinguished between the empirical realm where they applied and the metaphysical realm where they did not. But since he philosophized only about the metaphysical realm he comes across as an irrationalist.

1 Life

Son of a wealthy Jewish family, Shestov was born Yehuda Leib Shvartsman in Kiev. As a student, he was primarily interested in political and social questions. Because of his radical political views, he had to transfer from a gymnasium in Kiev to one in Moscow. He studied science and mathematics and then law at Moscow University, but completed his studies at Kiev University. His doctoral dissertation was on factory legislation; because it described the appalling condition of the workers it was rejected by the Board of Censors in Moscow as revolutionary. Shestov graduated with the degree of Candidate, not Doctor, of Law in 1889. He was licensed to practise law, but never did. He joined the army and then entered his father's textile business. In 1895, he had a nervous breakdown brought on by a combination of business pressures (he saved the firm from bankruptcy) and unhappy romantic involvements with two Gentile women, one after another, whom his father would not allow him to marry. To recover his health, Shestov went abroad in the spring of 1896. In Rome, he fell in love with a Russian Orthodox medical student, Anna Elezarovna Berezovskaia. They lived together and had two daughters. In 1907, they were married in London. Shestov did not tell his parents about Anna and the children until 1914, living apart from them, sometimes in different cities, for months at a time. Shestov also had an illegitimate son, who lived in Moscow with his mother. Shestov supported them and was a real father to his son.

In 1898, Shestov returned to Russia, bringing two completed manuscripts with him: *Shekspir i ego kritik Brandes (Shakespeare and his Critic Brandes)* and *Dobro v uchenii gr. Tolstogo i Fr. Nitshe (The Good in the Teaching of Tolstoy and Nietzsche)*. He lived in St Petersburg and Moscow and then resumed working in his father's business in Kiev. Shestov's acquaintance with Merezhkovskii, Rozanov, Diaghilev and Ivanov, and his lifelong friendships with Berdiaev, Bulgakov and Remizov date from this time (see Russian Religious-Philosophical Renaissance §1). Early in 1906 he came close to another nervous breakdown. He was then forty years old and still unable to live as he pleased. *Apofeoz bezpochvennosti (The Apotheosis of Groundlessness)* (1905) and *Nachala i kontsy (Beginnings and Endings)* (1908) reflect the hopelessness and despair that overwhelmed him. Between 1910 and 1914 he lived in Switzerland with his family and worked on *Sola Fide (By Faith Alone)* and *Vlast' kliuchei (The Power of the*

Keys). When the First World War broke out, they returned to Russia and settled in Moscow. In mid-1918, they fled to Kiev, then under German control. He gave a course on Greek philosophy at the University of Kiev and was awarded an honorary doctorate by the University of Simferopol. In February 1919, Kiev was 'liberated' by the Red Army.

The Bolsheviks considered Shestov a revolutionary writer and offered to publish *Potestas Clavium* if he would add a brief introduction defending Marxist doctrine, but he refused. In the autumn of 1919 the Shestovs emigrated, reaching Paris by a round-about route in 1920. Shestov was almost unknown there, but three articles, published in French, on Dostoevskii, Tolstoi and Pascal, brought him a European-wide reputation. The German Nietzsche Society elected him its honorary president and he was invited to lecture all over Europe. He was also elected to the Kant Society. His books were translated into French, German and other European languages. He taught at the Institut des Etudes Slaves and in the extension division of the Sorbonne, and associated with leading European intellectuals, including Husserl, who became one of his best friends despite their intellectual differences. It was at Husserl's urging that Shestov read Kierkegaard. Shestov's last article, 'In Memory of a Great Philosopher', was a tribute to Husserl, who had just died.

Politically Shestov was a liberal or a moderate socialist. After all, politics and economics belonged to the empirical realm. In 'Chto takoe bol'shevizm?' (What is Bolshevism?) (1920), he described Soviet rulers as reactionary, destructive and parasitical, emphasized their hostility to freedom, and pointed to the 'paradox of idealists who believe only in crude physical force'. In 'Menacing Barbarians of Today' (1934), Shestov compared the Nazis to the Tartars and maintained that civilization entailed the triumph of the spirit over force.

There is a personal dimension to Shestov's lifelong campaign against reason and morality - the double life he led for seventeen years and long-standing tensions with his father. At 12 or 13 Shestov was kidnapped by radicals and held for ransom. Apparently, this was a hoax to raise funds and Shestov was involved in the plot. Perhaps suspecting this, his father refused to pay. After six months Shestov was released unharmed. The battle of wills between father and son is significant, especially since Shestov lost. It is almost as if his writings were an outlet for his rage, not only against his father but against authority and 'necessity' in any form. Shestov's interpretation of the authors he treats is highly personal. He highlighted episodes or statements that resonated with his own experience, repeated them over and over again, and omitted others of equal or even greater importance.

2 Early writings

Shestov's early writings treated issues that were to occupy him all his life. In his first book, *Shekspir i ego kritik Brandes*, Shestov discussed the meaning of tragedy, the limits of positivism and Kantianism, and the indifference of science to life, giving as an example a brick that falls on someone's head and kills him. The law of gravity can explain why the brick fell, he said, but not why it fell on that particular man, nor does it care. Disputing Brandes' contention that tragedy is meaningless, Shestov argued that tragedy has a higher purpose - spiritual development or moral edification. He rejected this idealist interpretation in his books on Nietzsche, but came back to it, in a way, later on. A tenet of Shestov's religious existentialism is that suffering is the beginning of awakening. He also stated that philosophy begins in despair, not in wonder, as the Greeks believed.

Shekspir i ego kritik Brandes begins and ends with a quotation from Nietzsche, but Shestov had not yet assimilated Nietzsche's ideas. On first reading, Shestov did not understand *Beyond Good and Evil*. He found *The Genealogy of Morals* profoundly disturbing and searched for ways to combat Nietzsche's 'terrible, pitiless thought'. But then he learned about Nietzsche's sickness; 'on this day, I understood'. Reading Nietzsche sensitized Shestov to 'Nietzschean' qualities in Dostoevskii and accelerated Shestov's rejection of philosophical idealism and moralism (see Dostoevskii, F.; Nietzsche, F.).

In *The Good in the Teaching of Tolstoy and Nietzsche*, Shestov contrasted Nietzsche's passionate search for truth 'beyond good and evil' with Tolstoi's 'cowardly' submission to idealist pieties (see Tolstoi, L.N.). As Shestov tells it, Tolstoi was appalled by the poverty he saw in Moscow, but rather than admit his helplessness, he retreated to his estate to perfect himself. From then on, Tolstoi preached the identity of goodness and God, and tried to impose his self-denying morality on others. By contrast, Nietzsche's sickness led him to realize the futility of lofty ideals. The sickness was unjustified; Nietzsche had lived a virtuous life, but that was Shestov's point - great suffering is inexplicable and arbitrary. From personal experience Nietzsche learned that nature is cruel and that

God (goodness) is dead. But then Nietzsche lost his nerve and created a new idol - the Superman. Nevertheless, Shestov concluded: 'Nietzsche has shown the way. We must seek what is *higher* than compassion, what is *higher* than good. We must seek God' ([1900] 1969: 140).

In his next book, Shestov treated Dostoevskii and Nietzsche as 'underground' thinkers and spiritual twins. Dostoevskii's defining experience was hard labour and exile in Siberia, followed by his discovery of his own egoism upon his return to St Petersburg. In *Zapiski iz podpol'ia (Notes From Underground)* (1864) the protagonist declares that the whole world could 'go to pot' as long as he had his regular cup of tea. In *Crime and Punishment* Raskol'nikov asserts that there are two moralities, one for ordinary people, the other for extraordinary people like himself. Therefore, he was entitled to murder a 'useless' old woman because he needed her money. Nietzsche's 'underground' was illness, physical pain and loneliness. Like the protagonist of *Notes From Underground*, Nietzsche honestly and openly admitted that the happiness of humanity did not interest him. Both writers realized that egoism negates reason, conscience and idealism. Theirs was a '*morality of tragedy*', as distinct from a 'morality of *commonplaceness*'. Circumstances, not innate nobility, forced them into it.

Shestov believed that social changes will never banish tragedy from life and that to deny suffering is to deny reality. Philosophy's task, therefore, was not to preach humility, submission, renunciation or self-sacrifice, but to teach people not 'to transfer all the horrors of life into the sphere of the *Ding an sich*'. In *Apofeoz bezpochvennosti*, a compilation of 168 numbered sections, Shestov wrote: 'The business of philosophy is to teach men to live in uncertainty - man who is supremely afraid of uncertainty, and who is forever hiding behind this or the other dogma' ([1905] 1920: §11). In 'Creation From the Void', an essay published in *Nachala i kontsy (Beginnings and Endings)* (1908), Shestov praised Chekhov precisely because he did not offer a consoling ideal; his protagonists were people who lost all hope. In 'The Gift of Prophecy', Shestov pointed to prophecies of Dostoevskii, Tolstoi and Solov'ëv that did not come true. In *Velikie kanuny (Great Vigils)* (1911), Shestov interpreted the life and work of Sologub, Ibsen, William James and Tolstoi (as creator and destroyer of worlds) and criticized Kantian and positivist theories of knowledge.

Nietzsche was one of Shestov's lifelong reference points. He seconded Nietzsche's attack on Socratic rationalism (for different reasons), and claimed that it was Spinoza who murdered God. Shestov praised 'extraordinary' people who were given a second pair of eyes by the angel of death, or who thought in a second dimension. His protest against undeserved suffering turned into a conviction that for salvation 'works' don't matter. Shestov viewed Luther as a tragic figure like Nietzsche. He interpreted Nietzsche's 'will to power' as a variant of Luther's 'sola fide' and emphasized their mutual hostility to reason, righteousness and law (see Luther, M.). Dostoevskii was another lifelong reference point. When discussing people's willingness to give up their freedom for bread, security, and happiness, Shestov often alluded to 'The Grand Inquisitor' (see Dostoevskii, F.M. §4). When Shestov claimed that all metaphysical systems begin with freedom and end in necessity, he probably had Shigalëv's confession (in *The Possessed*) in mind. But he never invoked Dostoevskii's ideal of a community of faith. There is no church or synagogue in Shestov's philosophy. Focused on the solitary individual, Shestov rejected Solov'ëv's ideals of 'all-unity' and a supra-personal 'Godmanhood' (see Solov'ëv, V.S.). Moreover, Solov'ëv's orientation was too rational for him.

3 A leap into faith

Shestov's leap into faith is evident in *Sola Fide* (written 1911-14), *Vlast' kliuchei (The Power of Keys)* (1923), and *Na vesakh Iova (In Job's Balances)* (1929). Shestov considered *Sola Fide* a personal statement and did not publish it in his lifetime. The two sections, 'Greek and Medieval Philosophy' and 'Luther and the Church', reveal Shestov's immersion in Western philosophy and religion from the pre-Socratics to Husserl as well as Shestov's turn to the Bible. Describing Christian disputations on law and grace and on faith and works, Shestov pointed out that theologians attracted to Hellenic rationalism, ignored or denied miracles and mystery. *Vlast' kliuchei* reflects Shestov's horror at the First World War, not only because of the unprecedented mass slaughter, but because his beloved son was killed at the front. The title is an allusion to the keys that open and close the gates of heaven that Jesus gave to Peter. But, Shestov argued, Socrates and his successors also claimed the keys to heaven, substituting autonomous reason and autonomous virtue for the gods and maintaining that the virtuous man can be happy in a torture device (the bull of Phalaris). The Medieval Church wrested the keys away from the pagan philosophers; making the fatal mistake of trying to reconcile faith and reason, it ended up subordinating Scripture to reason. Now

the keys are being claimed by science, a development Shestov deplored. He blamed the war on Europeans' sacrilegious attempt to deify themselves and their reason in place of God. In 'Memento Mori', Shestov attacked Husserl for relying on self-evidences and logic, arguing that the law of identity, A = A, and the law of non-contradiction apply only to 'the middle zones of human and universal life, which do not at all resemble the polar and equatorial zones. The truths of one zone are not the truths of the other'. God's truths are not man's truths.

The epigram to *In Job's Balances* is Job's lament that his grief and calamity were heavier than the sands of the sea (Job 4: 2-3). Shestov's point was that human suffering weighs more than 'objective' truth. The foreword, 'Science and Free Inquiry', was about the limitations of science. Part I, 'Revelations of Death', comprises two essays: 'The Conquest of the Self-Evident: Dostoevsky's Philosophy', and 'The Last Judgment: Tolstoi's Last Works'. Dostoevskii and Tolstoi, Shestov argued, blunted their unique visions, by trying to fit them into the framework of commonplace truths. Dostoevskii transformed his insight that people actually like to suffer into the idea that suffering must 'buy' something, or redemption through suffering. Tolstoi, however, finally realized when he wrote 'The Death of Ivan Il'ich', 'Master and Man' and 'Father Sergei', that 'works' don't matter, that goodness isn't God. Shestov regarded death as an escape from 'omnitude' (allness, the One, total unity) to self-consciousness because everyone faces death alone.

Part II, 'Revolt and Submission', is comprised of fifty-two numbered sections. In the section about medieval debates on why God became a man, Shestov opposed the usual explanation, that there was no other way to save man, with his own: 'supernatural interference was only necessary because man had to be supported in his "mad endeavor", in his *unreasonable* audacity and self-affirmation' ([1929] 1975: 177; emphasis added).

Part III, 'On the Philosophy of History', comprises the essays 'Children and Stepchildren of Time: Spinoza in History', 'Gethsemane Night: Pascal's Philosophy' and 'Words That are Swallowed Up: Plotinus's Ecstasies'. Shestov held that there is no immanent Idea, or development in history, as Hegel maintained; it is all contingency. Pascal's method of seeing 'by lamentation' (Pascal was always in pain) he considered superior to Spinoza's dictum 'not to laugh, not to weep, not to curse, but to understand'. Spinoza was referring to human action and to the passions; Shestov, to misfortune. The essay on Plotinus emphasized the ecstatic insights that enable one to soar above knowledge, and Plotinus' resistance to the world-renunciation preached by the Gnostics. 'Suddenly' was one of Shestov's (and Dostoevskii's) favourite words; he used it to describe both tragedy and epiphany and associated 'suddenly' with the absurd, in other words, not part of the regular order.

4 Religious existentialism

In *Athènes et Jerusalem* (1938) Shestov summed up and developed ideas set forth in his previous works, including *Kierkegaard et la Philosophie Existentielle* (1936). His major theme was that philosophy and biblical revelation are incompatible. Therefore people must make an either/or choice between faith and knowledge. To this theme Shestov subordinated others: knowledge enslaves man; evil came into the world with knowledge; salvation is by faith alone; man must choose between the tree of knowledge and the tree of life; and God's freedom is infinite. Quoting Peter Damian's assertion that God can 'make what happened not to have happened' and Kierkegaard's *Fear and Trembling*, Shestov proclaimed that God can violate or suspend the laws he has established, be they the laws of nature or the Ten Commandments. For example, God commanded Abraham to kill Isaac. God can restore Job's children and undo Socrates drinking the hemlock and Nietzsche's madness (see Kierkegaard, S.A.).

Shestov associated the impossible with the absurd, attacked religions of consolation and claimed that both Christian and Jewish theologians have abandoned Scripture. As an example, he contrasted Isaiah's prophecy that the lion will lie down with the lamb with Aquinas' dictum, 'grace does not abolish nature'. One of Shestov's favourite biblical quotations was 'What things soever ye desire…ye shall have them' (Mark 11:24).

According to Shestov reason and morality demand resignation while the absurd and faith sanction daring. In this context, he quoted Kierkegaard on the difference between a 'knight of faith' and a 'knight of resignation', as well as Kierkegaard's admission that if he himself really had faith he would not have broken his engagement to Regina.

Shestov maintained that Western philosophy has struggled against the 'I', against individual existence, from its very beginning. Thales declared that all is God. Anaximander considered voluntary separation from the 'all' as a great sin, which doomed the individual to the greatest punishment, to death. This dreadful law inseparably links

birth and death. Necessity, uniformity, regularity and the depersonalizing philosophy of Descartes, Spinoza and Hegel all stem from it. By contrast, the Living God of Abraham, Isaac and Jacob, created man 'in his own image and likeness'. For man, as for God, everything is possible, including immortality, provided that he tear himself away from the seduction of reason. Not all questions can be answered, Shestov opined; God hides his truths in mystery.

To Shestov, the sin of Adam and Eve was choosing knowledge over life, not disobedience, as is usually maintained. Before the Fall they did not have to choose between good and evil, because there was no evil. Everything that God created was good. But the serpent deceived Eve. Knowledge does not increase human power but diminishes it. Evil and sin came into the world with knowledge. Shestov defined 'religious philosophy as the final supreme struggle to recover original freedom and the divine "very good", which was hidden in this freedom and which, after the Fall, was split into powerless good and our destructive evil' ([1938] 1966: 70). Now, instead of the creative 'Let there be!', there is only the plane of the petrified 'is'. And in the same spirit: faith abolishes reason. Faith is given to man to make him master in the world established for him by the Creator. Faith enables man to break through the self-evidences of reason and reach the freedom in which the impossible becomes the reality.

People subordinate God to reason and morality because they fear an omnipotent and capricious God, Shestov argued. Fear of the unknown leads people to take refuge in dogmatism. Luther created new catechisms and made Scripture the ultimate authority. Nietzsche deferred to necessity in the form of *amor fati*. Kierkegaard had all sorts of 'you musts'. Shestov denied any intention of attributing 'authority' to the Bible; he believed that Scripture 'decisively rejects the idea of authority'. God does not coerce man. Distinguishing between God's truth (freedom) and coercive truth (dogma), Shestov maintained that coercive truth destroys communication and leads to eternal hatred.

The utopianism and antinomianism of Shestov's *magnum opus* place him in the mainstream of the Religious-Philosophical Renaissance. On the other hand, despite his paeans to biblical revelation, his discussion of the Incarnation and his invocations of Christian theologians, he was not a Christian.

Shinran (1173-1263)

Shinran lived in thirteenth-century Japan, an age of socio-political turmoil, when the old order represented by imperial rule, aristocratic culture and monastic Buddhism was in the process of internal disintegration, and a vibrant age of military clans, popular culture and new schools of Buddhism, appealing to the disenfranchised, was beginning to emerge. Although Shinran's name is not found in the historical records of the period, he left many writings, including original works, commentaries, poetry and letters that contain religious and philosophical insights which had a great impact on subsequent Japanese life. His place in history was secured when in 1921 a collection of his wife's letters, attesting to their relationship over the years, was discovered in the archives of Nishi Hongwanji in Kyoto.

Shinran inherited the pious strain of Pure Land devotional Buddhism, a strain that existed in various subsidiary forms within the great monastic schools such as Tendai, Shingon, Hossō, Kegon and Sanron. In 1175, however, his teacher Hōnen made a radical break from tradition and declared the establishment of an independent Pure Land (Jōdo) School. As a consequence, the movement suffered societal criticism and political persecutions. Among Hōnen's followers, it was Shinran who deepened and expanded the Pure Land insights within the context of Mahāyāna Buddhist thought. His basic teaching may be summarized by such concepts as self-power and Other Power, the various stages of religious life, Amida Buddha as Other Power, and birth in the Pure Land.

The terms 'self-power' and 'Other Power' were first used by Tanluan (476-542) and developed by both Hōnen and Shinran as central concepts in Pure Land praxis. Self-power refers to the belief in one's capacity to attain enlightenment; it is rooted in the unconscious attachment to the ego-self in which every thought, act and speech aims at self-gratification. In contrast, Other Power, according to Shinran, is 'that which is free of calculation'. While self-power is manifested within the subject-object dichotomous mode, Other Power is an awakening to a non-dichotomous reality, such that one sees things, including the self, free of myopic self-centredness. Religiously, Other Power is symbolically represented by Amida, the Buddha of Immeasurable Life and Light. Ultimately, self-power cannot be recognized apart from appreciating Other Power, and the latter cannot be fully realized without exerting the former to its utter, breaking limits. The contrast between the two is not unrelated to Heidegger's distinction between calculative and meditative thinking (see Heidegger, M.), although they are not religious categories; calculative thinking is epitomized in science and technology, and meditative thinking in poetry as a form of disclosure.

The aim of the Pure Land path, then, is abrogating self-power for Other Power as the center of one's life. This transformation involves the proper understanding of Amida and Pure Land, whereby the 'other' is not to be understood in the conventional subject-object sense. Shinran explicates the two in the opening lines of the chapter on True Buddha and True Land of his major work, *Kyogyoshinsho (Teaching, Practice, Faith and Realization)*, as follows:

> Reverently contemplating the true Buddha and the true land, I find that the Buddha is the Tathāgata of inconceivable light and that the land also is the land of immeasurable light.
>
> (*Kyogyoshinsho*, in Ueda 1987, III: 395)

While the Buddha and Pure Land may appear to be objectified realities seen within a subject-object framework, true appreciation for both occurs when the reality of karma-bound self is illuminated through their working. It is not the case that there exists a being called Buddha who emanates rays of light, nor is there a place called Pure Land radiating light in all directions; rather, light which is regarded as 'the form taken by wisdom' (*prajnā*) illuminates the 'darkness of ignorance' (*avidyā*) within, thereby liberating the self from its binding powers. When this light is personified, it is called Amida Buddha; and when it is localized, the Pure Land. This dynamic working of reality in the midst of *samsāra* accords with the basic definition of Buddhahood traditionally given in East Asia: 'self-awakening and awakening of others, the activity of awakening unfolding without end' (*jikaku-kakuta kakugyō-gūman*).

The transformation of a samsaric being of ignorance to a person of true awakening in the Pure Land mode involves a spiritual evolution which Shinran called the 'transformation through the three stages' (*sangan-ten'yu*), based on

the praxis stipulated in three basic vows among the forty-eight vows fulfilled by Amida Buddha: the 19th, 20th and 18th vows. To adapt the language of Kierkegaard's stages of life's way (see Kierkegaard, S.A.), the 19th may be called the ethical, the 20th religiousness 'A', and the 18th religiousness 'B'. The 19th vow requires of a devotee a deep commitment to enlightenment, good works and sincere desire for birth in the Pure Land. When such self-power activities are recognized ultimately as fruitless for the truly religious life, one turns to the 20th vow, devised for those resigned to their lack of spiritual capacity and relying wholly on the sole invocation of *nembutsu* (the holy name of Amida), a religious act said to be 'planting the roots of merits'. But sooner or later, this act too is recognized for what it is: another calculation (*hakarai*) of self-power, unconsciously rooted in the ego-self and prideful of cumulative invocation. The realization of the futility of spiritual fulfillment according to the prescriptions in the 19th and 20th vows opens up the self to the working of Other Power, a transformation experienced within the parameters of the 18th vow. The person now experiences a 'leap' (*ōchō*) not from the relative to the relative but from the relative to the absolute; the primary impetus originates with the absolute, whether it is called true compassion, Other Power or Amida Buddha (see Absolute, the). As a consequence, one is endowed with a trusting heart and mind (*shinjin*).

Such a person attains 'birth in the Pure Land', which for Shinran had two implications. First, at the moment of being endowed with a trusting heart one attains a new life, here and now. It is said that although our defiled bodies remain within *samsāra*, our hearts and minds play in the Pure Land. Second, when the karmic life on this earth is exhausted at death, one attains birth in the Pure Land, which is simultaneous with attaining Buddhahood. This means that now, as a fully awakened being of wisdom and compassion, one returns to the world of *samsāra* to work for the deliverance of all existence. 'Birth in the Pure Land' understood in these two ways manifests the dynamic relationship between time and timelessness. Since the Pure Land symbolizes timelessness (eternity), it is inseparable from time (*samsāra*) and manifests itself in time. A person thus can have an experience of timelessness while remaining in time as a karma-bound being. But when karmic life is exhausted and Buddhahood realized (timelessness), one cannot help but identify with every moment of time (*samsāra*) (see Eternity).

Going to the Pure Land and returning to *samsāra* are the fullest expressions of the life of *bodhisattva*, philosophically expressed as the simultaneous activity of ascent and descent. Both are made possible not by any human calculation but by the working of Other Power. This powerful working leads to the releasement of self-power, manifested in a person as humility, repentance and gratitude which form the core of a truly ethical life, established on the basis of interdependence and interconnectedness of all existence, both animate and inanimate.

Shintō

Shintō means the 'way of the kami *(gods)' and is a term that was evolved about the late sixth or early seventh centuries - as Japan entered an extended period of cultural borrowing from China and Korea - to distinguish the amalgam of native religious beliefs from Buddhism, a continental import. Shintō embraces the most ancient and basic social and religious values of Japan. It is exclusively Japanese, showing no impulse to spread beyond Japan. The exportation of Shintō would in any case be exceedingly difficult since its mythology is so closely bound to the creation of Japan and the Japanese people, and since many of its deities are believed to make their homes in the mountains, rivers, trees, rocks and other natural features of the Japanese islands.*

Shintō comprises both great and little traditions. The great tradition, established in the mythology that was incorporated into Japan's two oldest extant writings, Kojiki (Record of Ancient Matters) and Nihon Shoki (Chronicle of Japan), both dating from the early eighth century, is centred on the imperial institution. According to the mythology the emperorship was ordained by the sun goddess, Amaterasu, who sent her grandson from heaven to earth (Japan) to found a dynasty 'to rule eternally'. The present emperor is the 125th in a line of sovereigns officially regarded, until Japan's defeat in the Second World War, as descended directly from Amaterasu.

Shintō's little tradition is a mixture of polytheistic beliefs about kami*, manifested in nature worship (animism), ancestor worship, agricultural cults, fertility rites, shamanism and more. Lacking a true scriptural basis, Shintō derives from the faith of the people, and from earliest times has had its roots firmly planted in particularistic, localistic practices. Thus it has always been strongest in its association with such entities as families, villages and locales (for example, mountains thought to be the homes of certain* kami *or, indeed, to be the* kami *themselves).*

1 *Kami*, people and nature

In Shintō belief there is no sharp distinction between *kami* and people - indeed some people, such as emperors, great heroes and ancestors, are regarded as *kami* - and both *kami* and people are joined together by their common habitation in the natural environment of the Japanese islands (although some *kami* in the mythology, including the sun goddess Amaterasu, reside in heaven). The human, natural and sacred realms merge. As the great eighteenth-century Shintō scholar Motoori Norinaga observed, '…the *kami* are spirits that abide in and are worshipped at the [Shintō] shrines. In principle human beings, birds, animals, trees, plants, mountains, oceans - all may be *kami*. According to ancient usage, whatever seemed strikingly impressive, possessed the quality of excellence, or inspired a feeling of awe was called *kami*' (quoted in Agency for Cultural Affairs 1972: 38).

Through Shintō, the Japanese people express their respect for all life as well as their appreciation of the beauties and powers of nature. And because certain elements and phenomena of nature, such as the sun, the moon, the wind and mountains, are regarded as *kami* and because nature as a whole is the principal home of the *kami*, nature is seen as 'good'. The Shintō view of nature has given a powerful stimulus to the arts and aesthetic tastes of the Japanese. Regarding nature as both beautiful and good, the Japanese have celebrated its qualities - especially the perishable beauties of the changing seasons, such as the cherry blossoms of spring and the maple leaves of autumn - in countless poems, paintings and other artistic media. Although Buddhism has also influenced the Japanese understanding of nature, the natural environment of Japan is first and foremost a world of Shintō (see Aesthetics, Japanese).

2 Worship of the *kami*

Kami are, for the most part, beneficent entities, requiring only that they be properly and respectfully attended to. Through worship, the people provide this attention and express their gratitude to the *kami*. The principal form of worship is the presentation of offerings to the *kami*, which can be rendered privately at home or publicly at a Shintō shrine. Items used as offerings include rice, other foods, *sake* and money.

People also say prayers and address petitions to the *kami*. The formal prayers, recited in archaic language by priests at shrines, typically praise the *kami* and express thanksgiving for the benefits they have bestowed. They may also include accounts of the lineages of the *kami* and describe the offerings being made to them. In their personal prayers and petitions, people make requests for such things as good health and personal success.

3 Purification

Shintō is a religion of rituals (see Ritual), and one of the central rituals is purification. The importance attached to purification in Shintō is readily observable, for example, in the procedures followed in preparing for worship and in worshipping. In approaching a shrine, one first performs ‘external’ or ‘outer’ purification - thus making oneself ready to enter the presence of the *kami* - by rinsing the mouth and hands with water at an ablution basin. Inside the shrine, the priest performs ‘internal’ or ‘inner’ purification in the form of exorcism by reciting prayers and waving a wand. Reflecting primitive, pre-ethical attitudes, Shinto regards both manifest defilements - such as bleeding, disease and death - and acts of evil or wrongdoing as ‘pollutions’ that must be ritually cleansed. Purification effects renewal: through purification, things are returned to their original states and proper identification with the *kami* is re-established.

Manifestations of the concern for purity and purification, deriving primarily from Shintō, can be observed in countless aspects of Japanese behaviour and life even today. The great attention given by the Japanese to bathing and general cleanliness is the most obvious of these manifestations, but they can also be found in such practices as the scattering of salt - a form of ritual purification - by sumo wrestlers before their bouts and the constant ‘cleansing’ of the utensils used in the tea ceremony. Although the tea ceremony, as it evolved during the medieval age, is generally thought to derive its spiritual essence from Buddhism, especially Zen, it is also thoroughly infused with Shintō or, more precisely, Shintō-like rituals of purification. We see this not only in the cleansing of the utensils but also in the precise and careful handling of water and fire, both of which are important agents of purification.

4 Shintō and Buddhism

According to the *Nihon Shoki (Chronicle of Japan)* in the early eighth century, Buddhism was introduced to Japan from Korea in 552. Undoubtedly the Japanese knew about Buddhism from a much earlier time, but it was in the middle or late sixth century that Buddhism was formally established in Japan, becoming in fact a principal carrier of continental culture during the long period of borrowing from China and Korea from the late sixth to mid-ninth centuries. It appears, as mentioned above, to have been the introduction of Buddhism to Japan that prompted the Japanese to coin the word Shintō for their native religious beliefs and practices. The construction of Buddhist temples in Japan also apparently inspired the Japanese to build sacred structures - which we call shrines - for Shintō (although there may have been some shrine construction from an earlier period). The continental architecture of Buddhism influenced Shintō architecture in various ways, particularly in later centuries. However, the structures of Shintō shrines (see §6) are based primarily on native styles and tastes that set them quite distinctively apart from Buddhist temples.

In addition to the architectural wonders of its temples, Buddhism also brought to Japan new types of religious paintings and statuary. Buddhist iconography is extremely rich and varied, and became a major component of art in Japan in succeeding centuries. Yet this is an area in which Buddhism exerted little influence on Shintō, for Shintō, with only minor exceptions, has not conceived of its deities in visual terms: that is, it has made virtually no attempt to portray the *kami* as entities based on, say, anthropomorphic or zoomorphic prototypes.

Buddhism’s view of the world could scarcely differ more from that of Shintō. Whereas Shintō celebrates life - and hence this existence - in all its manifold forms and creative vitality, Buddhism looks upon the world with the deepest pessimism as a place of incessant suffering. Suffering is caused because all things in the world are in flux, in a constant process of change (see Mujō). People seek to acquire things, to hold onto them, but this is impossible because of the impermanence of everything: nothing is substantial, nothing real. The result of human acqusitiveness is, inevitably, suffering. Although the various sects of Buddhism differ in the methods and the paths they recommend to their followers, they share the goal of achieving release from the cycle of life and death and hence from suffering (see Suffering, Buddhist views of origination of).

It is certainly an oversimplification to say, as has often been said, that Shintō is concerned with life and Buddhism with death, but there is a rough truth to this statement. Although Shintō mythology describes an underworld to which people must go upon death, essentially it has developed no theology about the afterlife. Death is a form of pollution, which like other pollutions requires ritual purification. Very likely a major reason why Shintō did not develop a theology of the afterlife is because Buddhism, upon its arrival in Japan, pre-empted this field. In any

case, Buddhism handles death - through funerals and periodic rites of mourning - to the point where its priests have in recent times been unflatteringly labelled the ‘undertakers of Japan’.

One reason, then, why Shintō and Buddhism have been able to coexist in Japan through the centuries is because they deal with essentially different realms, roughly categorizable as life and death. Another reason is that they have been partially syncretized. Syncretism is characteristic of East Asian religion and thought in general, and is certainly observable in Buddhism where, for example, we find the ninth-century founder of Shingon (True Word) Buddhism, Kūkai, writing a tract entitled *Jūjūshinron (The Ten Stages of Religious Consciousness)*, in which he ranks Confucianism, Daoism, and various sects of Buddhism in a hierarchy of ascending ‘consciousness’ culminating, at the highest level, in Shingon.

In both India and China, Buddhism recognized the ‘deities’ of other religions or systems of belief, including Confucianism and Daoism in China, by considering them as avatars of buddhas and bodhisattvas (see Buddhist philosophy, Indian; Buddhist philosophy, Chinese). It did this according to the concept of *honji suijaku* (original substance manifests traces), which became particularly important in Japan in regard to the association of Buddhism and Shintō. From the standpoint of Japanese Buddhists, *honji suijaku* meant that the deities of Buddhism (the substance) manifested themselves as the *kami* (traces) of Shintō. Thus, for example, the sun goddess Amaterasu was thought to be the ‘trace’ of Shingon’s cosmic Buddha, known in Japanese as Dainichi (Great Sun).

Fundamental to *honji suijaku* thought during the early centuries after its introduction to Japan was the belief that the buddhas and bodhisattvas were primary and the deities of Shintō were secondary. In the medieval age (1185-1573), however, there arose a movement within Shintō - as part of a larger Shintō revival - that sought to reverse this relationship, declaring the Shintō deities to be primary and the buddhas and bodhisattvas secondary. A good example of this reversal of the *honji suijaku* relationship can be observed in the late thirteenth century, when two attempts by forces of the Mongol dynasty of China to invade Japan, in 1274 and 1281, were defeated by typhoons that devastated the Mongol fleets. The Japanese believed these storms were *kamikaze*, ‘winds of the gods’, that were sent to protect Japan in times of greatest peril. Whereas for centuries the guardian deities of Buddhism had been looked upon as the principal protectors of the state, the function of state protection was thereafter shifted to the *kami* of Shintō.

5 The imperial institution

The mythology of Shintō proclaims that the sun goddess Amaterasu mandated her grandson - his name was Ninigi - to descend to Japan and establish a dynasty to rule the country eternally (although the actual dynastic founder and first emperor was Ninigi’s grandson, Jimmu). In any case, belief that Japan would be ruled forever by a single royal line became one of the most powerful myths in Japanese history, a myth that retained its potency as a tool of rule until it was shattered by Japan’s catastrophic defeat in the Second World War. Although through most of Japanese history the emperor has in fact functioned more as a ‘sacred legitimizer’ than an actual ruler (he has reigned rather than ruled), he, more than any other person or thing, has through the centuries symbolized ‘Japan’.

The significance of the imperial institution to Japan and the Japanese was given important new definition during the Shintō revival in the early medieval period. Following upon the assertion that the *kami* of Shintō, rather than the deities of Buddhism, provided protection for the state at the highest level, the fourteenth-century courtier Kitabatake Chikafusa declared in the opening lines of his history of Japan, *Jinnō Shōtōki (Chronicle of the Direct Descent of Gods and Sovereigns)*:

> Great Japan is the divine land. The heavenly progenitor founded it, and the sun goddess bequeathed it to her descendants to rule eternally. Only in our country is this true; there are no similar examples in other countries. This is why our country is called the divine land.
>
> (Varley 1980: 49)

Here Japan is extolled as a country superior to others because it has been ‘ruled’ from its founding by an unbroken dynastic line of sovereigns. As Chikafusa observed, other countries- such as India and China - have often been without sovereigns or have suffered frequent dynastic changes. The belief in the superiority of Japan and the Japanese centred on Japan’s ‘unique’ imperial institution, implicit in Chikafusa’s declaration, was sustained into the modern age, becoming the core of the *kokutai* (national polity) ideology that was officially promoted by

Japanese governments until the end of the Second World War (see Sovereignty).

6 The shrine

Probably the best known symbol of Shintō is the *torii* or 'bird perch' entranceway to a shrine. This entranceway supposedly has its origins in the mythology, where we read that a perch was erected for a cock to crow and signal the commencement of entertainment organized by the other gods in order to lure Amaterasu out of a cave in which she had secluded herself.

Shintō shrines are of a great variety, constructed in many diverse locations. At the base of society, in the villages and towns, shrines are found primarily in natural settings removed from most human habitation. These shrines seem to merge with nature in the same way that the human realm merges with the natural and sacred realms (see §1).

Shrines are the homes of *kami* and the places where offerings are made and prayers recited. Although some shrines are quite elaborate, comprising many buildings and covering extensive areas, the shrine at its simplest has an inner sanctuary, where the symbol of the resident *kami* (or symbols, if the shrine houses more than one *kami*) is housed, and an outer area for offerings and prayers. All shrines also have an ablution basin (see §3) where worshippers perform external purification. Worshippers do not enter the shrine buildings; only priests are allowed in them.

Although it may be difficult to perceive it in those located in congested cities, the shrine is always designed to evoke a sense of mystical unity with the *kami* and indeed with the land of Japan itself, the home of the *kami*. Shintō, represented by the shrine, constitutes the very basis of Japanese civilization.

Shōtoku Constitution

The Shōtoku Constitution is the earliest fundamental political document of Japan. Promulgated in AD *604, it is ascribed to the regent Shōtoku, who was also a devout Buddhist and philosopher. The document reflects the influences of Confucianism, Buddhism, Daoism and Legalism in its various provisions; it is strongly marked by Chinese thought rather than being influenced by Shintō. Not a constitution in the modern sense, the document is rather a set of ideals, guiding principles and basic requirements for those in government. As well as helping to lay the foundation for a unified Japan, the Constitution also marks the beginning of a period of assimilation of Chinese culture and philosophy.*

The Shōtoku Constitution was, according to tradition, promulgated in AD 604. Also called the Constitution in Seventeen Articles, it is ascribed to Shōtoku (574-622), a philosopher and a devout Buddhist as well as a statesman, who served as regent of Japan under the Empress Suiko. Before this time, Japan had not existed as a nation but had been divided into autonomous regions and clans, whose chiefs vied with one another for hegemony. With his Constitution, Shōtoku sought to establish Japan as a unified nation under the sole authority of the imperial throne, and to ground its conduct of government upon universal principles which he found in Buddhism and classical Chinese philosophy.

The Shōtoku Constitution is not a constitution in the modern and technical sense of a set of principles formally limiting the extent of legislation and formally grounding the legality of other laws. It is instead a set of ideals, guiding principles and basic requirements for the officials who exercise governmental powers.

The Constitution consists of seventeen articles, as follows:

Article 1 declares harmony to be a principle of governance within a hierarchical order and promotes the discussion of public affairs.
Article 2 exhorts the reverence of the Three Treasures of Buddhism, namely the Buddha, the Law and the Community of Practitioners, as ‘the final refuge of all living beings’ and ‘the ultimate foundation of all nations’.
Article 3 compares the lord to Heaven, the vassal to Earth and enjoins the vassal to obey the imperial commands scrupulously.
Article 4 enjoins the ministers and functionaries to base their conduct upon decorum.
Article 5 warns against the settling of law-suits under the influence of bribery.
Article 6 emphasizes the importance of moral integrity on the part of officials, and admonishes them not to resort to self-promoting deceptions.
Article 7 lays down the policy of honouring the wise in the management of bureaucracy.
Article 8 seeks to impress officials with the importance of diligence and punctuality.
Article 9 declares trustworthiness among vassals to be ‘the basis of righteousness’ on which the success or failure of government depends.
Article 10 calls for the cessation of anger, resentment and self-righteousness: ‘For everybody has a heart, and every heart has its own attachment. Their right is our wrong, our right, their wrong.’
Article 11 stresses the importance of reward and punishment according to deserts.
Article 12 forbids provincial governors and district administrators to levy taxes for themselves, and reserves taxation as a prerogative of the sovereign.
Article 13 commands the officials to execute public affairs responsibly, stating that their absence, for reasons official or personal, does not excuse them from their duties.
Article 14 points out the evils of envy at the sight of the promotion of those with superior intelligence or ability.
Article 15 calls for the setting aside of private motives, which otherwise would lead to resentment and discord.
Article 16 states that the conscription of labour for public works should not interfere with the peasants’ agricultural production.
Article 17 points out the need of public discussions of weighty public affairs.

In this set of principles the influence of Confucianism is prominent. Harmony, decorum and trustworthiness, which are the bases of Articles 1, 4 and 9, are central elements of Confucian ethics (see Confucian philosophy, Japanese; Confucian philosophy, Chinese). Article 2 is striking in its commitment to Buddhism; Buddhists vow to take

refuge in the Three Treasures (see Buddhist philosophy, Japanese). Articles 5, 11 and 12, concerned respectively with the fair enforcement of laws, reward and punishment, and taxation, betray the influence of Legalism (see Legalist philosophy, Chinese). The call to abandon desires in Article 5 and the relativity of conventional valuation in Article 10 sound Daoist (see Daoist philosophy). In contrast with the marked presence of Chinese thought in the Constitution, the influence of Shintō, the indigenous folk religion, is characteristically absent.

The philosophical interest and significance of the Shōtoku Constitution lie primarily in the following three areas:

(1) Exactly what universal principles of East Asian continental thought were applied, and how were they applied, to the political situation in the southwestern half of the Japanese archipelago at the formative stage of Japan in the early seventh century? Did the urgent practical need for political reform dictate the utilizations of ideas and ideals of political philosophy as instruments, or did the political situation serve as the medium through which to implement the ideas and ideals?
(2) How are the ideas and ideals culled from the different sources of Mahāyāna Buddhism, Daoism, Confucianism and Legalism related one to another in the ways in which they inform the Constitution? Do the influences of Confucianism and Buddhism, for instance, simply coexist side by side, or are they reconciled with each other and integrated into some coherent pattern? If so, what is that pattern?
(3) How did the Constitution, the earliest politically authoritative articulation of an ideology, set a precedent for the subsequent development of Japanese thought and culture?

On these three issues, no clear scholarly consensus has yet emerged. However, scholars have to a considerable extent overcome healthy scepticism concerning the prior issues about the date and the authorship of the Constitution, and have canvassed a vast body of Chinese literature, including Chinese versions of Mahāyāna *sūtras*, in order to identify the sources of verbal borrowings, echoes and allusions with which the text of the Constitution abounds. The entire text of the Constitution, written in highly stylized classical Chinese, has been preserved as a quotation in the *Nihon shoki (Chronicles of Japan)*, and is there attributed to Shōtoku.

Among other achievements of the Shōtoku regency are the construction of Buddhist temples, the writing of commentaries on three Mahāyāna *sūtras*, the institution of the Twelve Cap-ranks of bureaucracy and the inauguration of official envoys to China. The Constitution, together with these achievements, contributed much to the transition of Japan from a divided tribal society to a united nation, the adoption and assimilation of Chinese civilization including philosophy, and the transformation of Japan into a land of Buddhism.

Shpet, Gustav Gustavovich (1879-1937)

Gustav Shpet was the first Russian philosopher to take up Edmund Husserl's idea of pure phenomenology as prima philosophia *and develop it in several directions. Thus, in his most important phenomenological work Iavlenie i smysl (Appearance and Sense) (1914), he outlined his 'phenomenology of hermeneutic reason' on the basis of Husserl's* Ideas 1. *In this theoretical framework he formulated, between 1914 and 1918, hermeneutic and semiotic problems, which in the 1920s he elaborated more specifically within the fields of philosophy of language and theory of art. In doing so he took up ideas from other philosophical movements, particularly Dilthey's hermeneutics and Wilhelm von Humboldt's philosophy of language.*

Shpet's reception of phenomenology has to be seen in the context of Russian intellectual and cultural life during the first two decades of the twentieth century. The Platonic 'Moscow Metaphysical School' (which included V. Solov'ëv and S. Trubetskoi) provided the intellectual atmosphere in which his turn to Husserl's phenomenology took place, and his ideas on theories of language and signs are close to ideas of the contemporary movement of Russian Formalism. Through his phenomenological and structural theories he influenced Prague structuralism via the 'Moscow Linguistic Circle', and is seen as a precursor to Soviet Semiotics.

1 Life

Gustav Shpet, founder of a phenomenological movement in Russia, was born in Kiev. He studied there at the Vladimir University from 1901-5 and finished his studies with a monograph entitled *Problema prichinnosti v Iume i Kante (The Problem of Causality in Hume and Kant)*. In 1907 he moved to Moscow, and taught at Moscow University from 1910 onwards. During a stay in Göttingen (1912-13) where he studied with Husserl he turned to Husserl's transcendental phenomenology. His first phenomenological publication *Iavlenie i smysl (Appearance and Sense)* (1914) marked the beginning of a productive reception of Husserl's phenomenology in Russia. In 1916 he had his viva on his Master's thesis *Istoriia kak problema logiki (History as a Problem of Logic. Part I)*. In 1918 he finished his manuscript on *Germenevtika i eë problemy (Hermeneutics and its Problems)*, in which he critically presented the problems of hermeneutics as they have developed throughout history from antiquity (especially in Origen and Augustine) to modern times, thereby at the same time elaborating the basic outline of his 'hermeneutical philosophy': a philosophy which is caught in the field of tension exerted, on the one side, by Husserl's 'Phenomenology of Reason' and, on the other, by Dilthey's 'Philosophy of Life'.

After the Revolution of 1917, Shpet was active in many different fields. He received a professorship of philosophy at Moscow University. In 1920 he joined the 'Moscow Linguistic Circle' (MLK), a centre of Russian Formalism (see Russian literary Formalism), and in 1921 was appointed director of the Institute for Scientific Philosophy, a new research institute at Moscow University. Expelled from there in 1923 for political reasons, he concentrated his activities on the State Academy of the Arts (GAKhN), whose vice-president he was until 1929, and whose Department of Philosophy he temporarily led.

His most important contributions to the theory of art and language are his *Ėsteticheskie fragmenty (Aesthetic Fragments)*, published in 1922 and 1923 in Petrograd, and *Vnutrenniaia forma slova (The Internal Form of the Word)* (1927). *Ėsteticheskie fragmenty* includes a phenomenology of 'living discourse' and an analysis of those rules which determine the constitution of meaning in poetic discourse. These phenomenological and structural analyses of language, which aim to construct a poetics, were further developed through a critical assessment of Humboldt's philosophy of language in Shpet's last substantial work *The Internal Form of the Word*.

During a 'cleansing' of the GAKhN in 1929, Shpet was forced to retire, but was still able to work for a while as a translator, editor and critic. It was then that he translated Dickens, Byron and Shakespeare into Russian. In March 1935 he was arrested by the NKVD and charged with having led an anti-Soviet group during his time at the GAKhN in the 1920s. After a lengthy detention he was exiled for five years to Eniseisk, later to Tomsk. Here in 1937 he finished his Russian translation of Hegel's *Phenomenology of Spirit*. In October of the same year he was again arrested and shot by the NKVD.

2 Development towards phenomenology

Representative of Shpet's notion of philosophy before his turn to phenomenology (and of expectations he then had

for a future reform of philosophy and psychology) is his article ‘Odin put’ psikhologii i kuda on vedët’ (One Method of Psychology and Where It Leads To), published in 1912. He criticized the prevailing trend of an experimental and explanatory psychology for having replaced ’lively and concrete facts’ with ’empty schemata and abstractions’. Only a descriptive psychology which focuses on the pure data of consciousness would be able to fathom psychic life in its concreteness and totality. He saw the basis for such a new direction in psychological thinking in Wilhelm Dilthey’s *Ideas on a Descriptive and Analytical Psychology* (1894) (see Dilthey, W.) and he argued that there was a particular style of philosophizing, that would correspond to this new type of philosophy which takes into account the totality of psychic life: a ’realistic metaphysics’ whose task it would be to grasp ’the real in its true essence and its totality’. Shpet thought that such a philosophy, which draws on the evident facts of ’inner experience’, had been realized in important movements of nineteenth and early twentieth century Russian philosophy. Philosophers of the ’Moscow Metaphysical School’ are mentioned as typical exponents of this trait in Russian thought (see Solov’ëv. V.S.).

Another, no less important, influence on Shpet’s reception of Husserl was his interest in the logic of the historical sciences. During his stay in Göttingen (1912-13) he found in Husserl’s phenomenology the theory he had been looking for, and his hermeneutical interest motivated him to try to develop Husserl’s ’Phenomenology of Reason’, as outlined in *Ideas Pertaining to a Pure Phenomenology, volume 1* (referred to as *Ideas 1*) into a theory of hermeneutic reason which focuses on the problem of understanding signs.

Although the ideas Shpet encountered in Göttingen primarily concerned *transcendental* phenomenology - the seminar on ’Nature and Spirit’, which Shpet attended with other influential phenomenologists like Roman Ingarden and Hans Lipps, certainly met his hermeneutical interests - on the other hand, the *ontological* trend in the intellectual atmosphere among Husserl’s fellow students in Göttingen also has to be taken into account (see Phenomenological movement §§3-4).

3 Concept of phenomenology

Shpet’s encounter with Husserl’s phenomenology in the light of his expectation of a reform of philosophy and psychology leads to a peculiar notion of phenomenology, which is documented in *Iavlenie i smysl (Appearance and Sense)* (1914). On the one hand, the Russian phenomenologist tries to reconstruct Husserl’s noetic-noematic studies within the framework of an ontological question, based on the Neoplatonism of the ’Moscow Metaphysical School’; on the other he demonstrates the incompleteness of Husserl’s analyses of objects, as given in *Ideas 1*, and completes these analyses with his own. The ’noematic sense’ intended in acts of consciousness, as presented by Husserl, presupposes for Shpet a class of intentional experiences hardly dealt with in *Ideas 1*; acts of consciousness through understanding, which play a role in the constitution of all classes of concrete objects. The structure of these ’hermeneutic acts’ is illustrated by a range of phenomena which are only of minor importance in *Ideas 1*: by the mode of appearance of items of practical use, the specific character of historical sources and the understanding of linguistic utterances. Thereby Husserl’s ’Phenomenology of Reason’ meets Shpet’s endeavour to find a basis for historical cognition in scientific logic, and eventually to prepare a grounding of the humanities, in other words, to prepare an analysis of their conceptual frameworks and most important methods.

Appearance and Sense marks the early phase of Shpet’s reception of Husserl. Here he outlines his project of a ’phenomenology of hermeneutical reason’. The ensuing works on hermeneutics, philosophy of language and theory of art, published or written between 1916 and 1927, can be seen as a further development of such a hermeneutical phenomenology, whose leading idea is the correlation of signs (as combinations of expression and meaning) and sign-interpreting consciousness.

Shpet also characterizes his project as a semiotic ’Philosophy of Culture’ in which language, art, myths and manners are to be described as systems of signs. He develops the basic model of a sign out of Husserl’s concept of linguistic expression, which acts as prototype for all other forms of signs. The idea of a ’purely logical grammar’, which formulates laws for the grammatical meanings of natural languages, should be applied analogously to all the other cultural systems.

4 Hermeneutics, philosophy of language and poetics

The concrete form of Shpet’s phenomenology of hermeneutical reason in his philosophy of language and his

poetics was also much influenced by Dilthey's 'Philosophy of Life'. In his hermeneutical philosophy, as outlined in the manuscript *Germenevtika i eë problemy (Hermeneutics and its Problems)*, he worked with Schleiermacher's, Boeckh's and Dilthey's theories of understanding (see Hermeneutics §§2-4; Schleiermacher, F.D.E.). Above all, he tried to deepen and refine Dilthey's late grounding of the humanities - then the culmination in the development of hermeneutics - with insights in the domain of semiotic theories, which he found not only in Husserl's first *Logical Investigation* on *Expression and Meaning*, but also in other semantic works of the Brentano School (Marty and Meinong especially). A combination of Husserl's semantics with Dilthey's hermeneutics would be an enrichment for both sides, as Shpet wrote at the end of the manuscript. The theory of understanding could find a new answer to the question of the mutual relation of the different methods of interpretation, whereas semantics would experience in this combination a 'philosophically lively and concrete embodiment'.

This actualization of Husserl's semantics, with a hermeneutical intention, has left its traces in Shpet's *Ėsteticheskie fragmenty*. With this tripartite work he entered the contemporary discussions on literary theory, as initiated by Russian Formalism. He was particularly concerned with the definition of the specific character of poetical discourse as opposed to others, be they scientific, rhetorical or everyday discourses. If one puts this question phenomenologically, one has to ask under what condition a linguistic utterance appears as artistic or poetic to a listener or reader. Since a poetic utterance is experienced only as a contrast to everyday use of language, one has to analyse first the reception of everyday language. This is the procedure Shpet follows in the second part of *Ėsteticheskie fragmenty*. In the description here of the various forms and aspects of the understanding of language, the difference between understanding the message and understanding the author of the message plays a pivotal role.

Here only the description of the understanding of language is called a phenomenological analysis. In opposition to this, Shpet presented his description of the structure of linguistic expression as 'ontology of the word', which he, in turn, subsumed under a general theory of semiotics. In this confrontation between a phenomenological inquiry, which is confined to the side of experience, and an ontology, which focuses on the object, the ever increasing influence of Husserl's early concept of phenomenology on Shpet becomes visible. In Shpet's 'ontology of the word' a particular concept of structure is of central importance. 'The structure is a concrete construction whose individual parts can vary in their extent and even in their quantity, but not a single part of the whole *in potentia* can be removed without destroying this whole' (1922-3: II, 11). By 'structure of the word' Shpet did not mean the morphological, syntactic or stylistic construction, in short, not the arrangement of linguistic units 'in the plain', but 'the organic, depth-wise, as it were, arrangement of the word - from the sensually conceivable wording to the eidetic object' (1922-3: II, 11). Therefore the word-structure consists not only of the relations between wording and meaning, but also of the relations between meaning and 'object' (the latter, as ideal object, being ontologically distinguished from concrete individual things).

When Shpet spoke of the structure of the *word*, he took it in the wide sense of the Russian expression for 'word', namely 'slovo'. 'Slovo' is used not only for words but also for groups of words, sentences and combinations of sentences, even for literary texts and for the whole of a natural language. Shpet used it with all these different meanings, yet was mainly concerned with the 'communicating word': meaningful discourse able to convey something to another person. Thereby Shpet took up Plato's definition of predicative statements, as the 'shortest and most simple *logos*'. Shpet saw its structure as follows:

In a simple predication the expression in subject position denotes a concrete, individual object; the predicate indicates a property belonging to this object. How such a sentence, consisting of a proper name (or other denominations) and a predicate, can have a sense and refer to objects, is clarified by Shpet through an analysis of the use of these expressions. In denoting speakers refer to a thing, in predication they say something about it. What can be said about this thing, and, conversely, which predications are impossible, is determined by the species to which the thing belongs. Therefore an act intending this species, which Shpet called also the 'eidetic object', is constitutive for the construction of a meaningful predication.

The central point of Shpet's theory of predication is that the meaning of the predicate can only be given in the act of predication, in so far as an assertion of meaning only happens in the interplay of the denoting of individuals and the act intending an eidetic object.

With these definitions Shpet outlined the 'word's' structure, which is common to factual or scientific

communicating, to rhetorical and to poetic discourse. The key to the specification of this general structure in the artistic and literary usage and formation of words, sentences and combinations of sentences, is to be found in Shpet's theory of linguistic functions; a theory which he developed through a critical assessment of Husserl's and Marty's philosophy of language. He started from three different functions of language which can be fulfilled by each type of discourse. Thereby in each case one function dominates the others. These three functions are the factual-communicating, the expressive and the poetic, in other words, the function working through the creative formation of language. (The idea of the creative character of language, which is most obvious in poetic discourse, is common to both Russian Formalism and Shpet's poetics, and can be traced back to Wilhelm von Humboldt's concept of language as *'Energeia'* (see Humboldt, W. von).

Depending on which of the three functions is dominant, discourse is either scientific (concerned with factual communication), rhetorical (concerned with influencing the emotions), or poetic (primarily concerned with the arrangement of linguistic expressions as such). The predominance of one of the three functions implies in each case a different mutual relation between the parts of the word-structure. Whereas, for example, in everyday language the arrangement on the level of expression aims primarily at structuring the expressed meaning, and thereby at the communication of facts, in poetic discourse all levels gain a relative importance on their own. The rhythmic forms and syntactic particularities of this discourse should be noticeable as such. On the other hand, the meaning expressed in poetic discourse is more dependent on those external forms of language: whereas the meaning of a factual - above all scientific - communication is not affected by each change of wording and syntactic arrangement, the 'poetic meaning' is far more sensitive to such changes.

5 Turning away from Husserl's concept of language

By giving pure logic, which deals with the condition of the possibility of science, a phenomenological foundation, Husserl excluded important aspects of living discourse. Shpet's project was more extensive than Husserl's in that he analysed scientific discourse as a possible form of discourse next to poetic, rhetoric and everyday discourse. This widening of the horizon entails a turning away from (not only a modification of) Husserl's concept of language. This becomes obvious when Shpet questioned a central presupposition of *Logical Investigations* - that scientific discourse can be marked off from living discourse. These two kinds of discourse are only tendencies, as Shpet emphasized; they are not fully realized in any empirical speech sample: 'Figurativeness is not only a trait of "poetry"… it is a general property of language, which belongs to scientific discourse, too'. 'The figurative and the literal can only be distinguished by tendency' (1922-3: III, 32).

The thesis of the irreducibility of figurative-ambivalent discourse has to do with Shpet's emphasis on the fact that thought is inseparably bound to language. With this concept of language as 'formative organ of thought', as outlined by Shpet in his interpretation of Humboldt of 1927, he turned away most clearly from Husserl's *Logical Investigations*, according to which 'the fact of being expressed is arbitrary for the meanings'.

Sidgwick, Henry (1838-1900)

Henry Sidgwick was a Cambridge philosopher, psychic researcher and educational reformer, whose works in practical philosophy, especially The Methods of Ethics (1874), brought classical utilitarianism to its peak of theoretical sophistication and drew out the deep conflicts within that tradition, perhaps within the age of British imperialism itself. Sidgwick was profoundly influenced byJ.S. Mill, but his version of utilitarianism - the view that those social or individual actions are right that maximize aggregate happiness - also revived certain Benthamite doctrines, though with more cogent accounts of ultimate good as pleasure, of total versus average utility, and of the analytical or deductive method. YetSidgwick was a cognitivist in ethics who sought both to ground utilitarianism on fundamental intuitions and to encompass within it the principles of common-sense ethics (truthfulness, fidelity, justice, etc.); his highly eclectic practical philosophy assimilated much of the rationalism, social conservatism and historical method of rival views, reflecting such influences as Butler, Clarke,Aristotle, Bagehot, Green, Whewell and Kant. Ultimately, Sidgwick's careful academic inquiries failed to demonstrate that one ought always to promote the happiness of all rather than one's own happiness, and this dualism of practical reason, along with his doubt about the viability of religion, led him to view his results as largely destructive and potentially deleterious in their influence.

1 Life

Henry Sidgwick's entire life fell within the reign of Queen Victoria and his entire career within the domain of Cambridge University, where he went from a brilliant undergraduate performance at Trinity College to become Knightbridge Professor of Moral Philosophy in 1883. He began his career as a classicist, but throughout his life extended his research and teaching into new disciplines: primarily moral theory, epistemology and metaphysics, political economy and political theory. His impact on the moral sciences at Cambridge was profound, and he was the guiding spirit behind Newnham College, one of England's first women's colleges. A long-standing member of the elite Cambridge discussion group, the Apostles, Sidgwick taught in a style that was, as W.R. Sorley put it, 'a training in the philosophical temper - in candour, self-criticism and regard for truth'. His best-regarded work has always been *The Methods of Ethics* (1874), but he also wrote major treatises on *The Principles of Political Economy* (1883) and *The Elements of Politics* (1891), as well as a primer on the history of ethics and numerous essays and reviews. Various posthumous works also appeared, thanks to the efforts of Eleanor Mildred Sidgwick (née Balfour), whom he had married in 1876 and who collaborated with him on many projects.

The sole interruption in Sidgwick's Cambridge career came in 1869, when he resigned his fellowship because he could no longer in good conscience subscribe to the Thirty-Nine Articles as required by law. Although he kept a lectureship and the tests were abolished in 1871, this was a formative event in his life, both stimulating and prefiguring his struggles with the foundations of ethics - as shown by his pamphlet on *The Ethics of Conformity and Subscription* (1870). His years of 'storm and stress' over religious questions led him from historical biblical criticism to philosophy and psychic research. He was a founder and the first president of the Society for Psychical Research, and his scientific investigations of purported psychical phenomena complemented his philosophical investigations into the 'deepest problems of human life', since he thought that evidence for personal survival of death might provide rational grounds for religious belief and ethical conduct.

2 Ethics and utilitarianism

In composing *The Methods*, Sidgwick thought of himself as emulating Aristotle, whose *Ethics* had 'reduced to consistency by careful comparison' the common-sense morality of Greece, treated not from the outside but as what he and others thought upon reflection. He wants to 'do the same for *our* morality here and now, in the same manner of impartial reflection on current opinion'. His aim is less practice than knowledge, merely 'to expound as clearly and as fully as my limits will allow the different methods of Ethics that I find implicit in our common moral reasoning; to point out their mutual relations; and where they seem to conflict, to define the issue as much as possible'.

Sidgwick's reflections often clash with earlier traditions, including utilitarianism, the empiricism, psychological egoism and reductionism of which he rejected. He maintains that the basic concept of morality - 'ought' or 'right' - is unique and irreducible, *sui generis*. Also, moral approbation is 'inseparably bound up with the conviction,

implicit or explicit, that the conduct approved is "really" right - that is, that it cannot, without error, be disapproved by any other mind'. He describes these 'dictates' or 'imperatives' in a largely internalist fashion as 'accompanied by a certain impulse to do the acts recognized as right', though other impulses are likely to conflict. Despite such debts to Butler, Clarke andKant, Sidgwick saw the issue of free will v. determinism (and other metaphysical issues) as largely irrelevant to ethics, since it is usually impossible, in deliberation, to regard the mere absence of adequate motive as 'a reason for not doing what I otherwise judge to be reasonable' (see Moral motivation §1; Praise and blame).

Judgments of ultimate good, rather than right, do not involve definite precepts to act or the assumption that we are capable of doing so, and leave it open 'whether this particular kind of good is the greatest good that we can under the circumstances obtain'. 'Ultimate good on the whole,' Sidgwick suggests, if 'unqualified by reference to a particular subject, must be taken to mean what as a rational being I should desire and seek to realize, assuming myself to have an equal concern for *all* existence' - in contrast to taking my own existence alone to be considered, as in 'ultimate good on the whole for me'. With greater Benthamite consistency thanMill, he argues that happiness (whether for the egoist or the utilitarian) should be interpreted hedonistically in terms of pleasure or desirable consciousness, and that this yields the best account of ultimate good (see Good, theories of the; Happiness; Hedonism).

Although not preoccupied with the moral faculty as such, Sidgwick is specially concerned with moral reasoning. A 'method' of ethics is not simply a principle or theory, but a rational procedure 'for determining right conduct in any particular case', for determining the rightness of an individual's actions by seeing whether the acts in question possess some property, which, on the basis of principle, provides the ultimate reason for the rightness of acts. The plain man, he holds, uses a jumble of different methods, insufficiently reflected upon. Though many think that conscience delivers immediate judgments on the rightness of particular acts ('perceptional' or 'ultra' intuitionism), Sidgwick has 'no doubt that reflective persons, in proportion to their reflectiveness, come to rely rather on abstract universal intuitions relating to classes of cases conceived under general notions'. But this 'dogmatic' intuitionism, on which 'the practically ultimate end of moral actions' is their 'conformity to certain rules or dictates of Duty unconditionally prescribed' and discernible with 'really clear and finally valid intuition', can also be subjected to further reflection and found wanting. In synthesizing its precepts, and 'without being disposed to deny that conduct commonly judged to be right is so, we may yet require some deeper explanation *why* it is so', yielding a third phase of Intuitionism:

> which, while accepting the morality of common sense as in the main sound, still attempts to find for it a philosophic basis which it does not itself offer: to get one or more principles more absolutely and undeniably true and evident, from which the current rules might be deduced, either just as they are commonly received or with slight modifications and rectifications.
>
> (*The Methods of Ethics* 1907: 102)

Thus Sidgwick famously reconciles intuitional or common-sense morality - the nineteenth-century opponent to utilitarianism - with utilitarian principles. There are self-evident practical principles, but they 'are of too abstract a nature, and too universal in their scope, to enable us to ascertain by immediate application of them what we ought to do in any particular case'. As reflection is followed out, apprehension changes; the 'self-evidence' of particular maxims of duty fades beside that of such abstract principles as 'what is right for me must be right for all persons in precisely similar circumstances' and 'I ought to prefer the greater good of another to my own lesser good'. The dogmatic intuitionist discovers that such rules as veracity, fidelity and justice require both qualification and further systematization by higher principles, which will also resolve the conflicts between and variable formulations of such rules. Utilitarianism can sustain the 'general validity' of such rules and correct for 'the defects which reflection finds in the intuitive recognition of their stringency'; it also 'affords a principle of synthesis, and a method for binding the unconnected and occasionally conflicting principles of common moral reasoning into a complete and harmonious system'. If reflection thus reveals utilitarianism as the view to which common morality 'naturally appeals for that further development of its system which this same reflection shows to be necessary, the proof of Utilitarianism seems as complete as it can be made' (see Intuitionism in ethics §2; Moral Justification; Utilitarianism).

Sidgwick allows that current morality should not be accepted *en bloc* as the middle axioms of utilitarianism. But

he insists that in both ethics and politics, utopian speculation is an ‘illimitable cloudland’, and we must start

> with the existing social order, and the existing morality as a part of that order: and in deciding the question whether any divergence from this code is to be recommended, must consider chiefly the immediate consequences of such divergence, upon a society in which such a code is conceived generally to subsist.
>
> (*The Methods of Ethics* 1907: 474)

Besides, it is not self-evident that universal benevolence ‘is the right *means* to the attainment of universal good’, since this end may be ‘self-limiting; may direct its own partial suppression in favour of other impulses’. Indeed, Sidgwick notoriously countenanced the idea of an ‘esoteric morality’, since in less than ideal utilitarian circumstances, a utilitarian could reason that ‘some of his conclusions should be rejected by mankind generally; or even that the vulgar should keep aloof from his system as a whole, in so far as the inevitable indefiniteness and complexity of its calculations render it likely to lead to bad results in their hands’ - a view that, Sidgwick admitted, is itself perhaps best kept esoteric. Such arguments continue to inspire both utilitarians and their critics, and suggest the difficulties of finding in Sidgwick’s focus on method any great confidence in the normal person’s capacity for moral self-direction. A ‘method’ straddles the distinction between ethical standards and decision-procedures; it admits of indirect (or two-level) utilitarianism, and only in this way addresses act v. rule utilitarianism, motive utilitarianism, and so on (see Consequentialism; Moral expertise).

It is ironic that Sidgwick assimilated both the epistemology and much of the social conservatism for which utilitarians had long castigated such intuitionists as Whewell: ‘Adhere generally, deviate and attempt reform only in exceptional cases in which… the argument against Common Sense is decisive’. As D.G. Ritchie noted,Sidgwick’s ethics and politics were decidedly ‘tame and sleek’ - the ‘method is Bentham’s; but there is none of Bentham’s strong critical antagonism to the institutions of his time’. Sidgwick even downplayed his own critical insights, if they veered too far from common sense. *The Methods* provides a clear and original defence of classical against average utility calculations in relation to optimal population size and future generations, but *The Elements* elides the issue in the search for common ground, a manoeuvre also made with respect to women’s equality and the utilitarian critique of nationalism.

3 The dualism of practical reason

Sidgwick’s philosophical intuitionism houses a number of presumptively compatible, abstract, self-evident truths: a universalizability principle, a principle of rational prudence to the effect that, *ceteris paribus*, one should be equally concerned with all temporal parts of one’s life, and the principle of rational benevolence, the basis for utilitarianism (somewhat questionably derived by enjoining aiming at good generally and taking the good of each as equally important). He anticipates many recent utilitarians in interpreting the universalizability principle, derived fromKant, as purely formal, meaning simply that whatever ‘is right for me must be right for all persons in similar circumstances’ and therefore as compatible with utilitarianism (see Impartiality). However, such concordances notwithstanding, the conflict between the methods of utilitarianism and egoism, unlike that between intuitional morality and utilitarianism, is real. In an essay on *The Methods*, he explains that along with

> (a) a fundamental moral conviction that I ought to sacrifice my own happiness, if by so doing I can increase the happiness of others to a greater extent than I diminish my own, I find also (b) a conviction - which it would be paradoxical to call ‘moral’, but which is none the less fundamental - that it would be irrational to sacrifice any portion of my own happiness unless the sacrifice is to be somehow at some time compensated by an equivalent addition to my own happiness.
>
> (‘Some Fundamental Ethical Controversies’ 1889: 483)

Each of these convictions has as much clearness and certainty ‘as the process of introspective reflection can give’ as well as a preponderant, if implicit, assent ‘in the common sense of mankind’.

Excepting the criterion of mutual consistency, both convictions could pass the most demanding tests for self-evident truths: careful reflection, clarity and precision, and consensus among competent judges.Sidgwick therefore regards this as a ‘fundamental contradiction in our apparent intuitions of what is Reasonable in conduct’ and concludes, in the first edition of *The Methods*, that unless a way be found to reconcile ‘the Individual with the Universal Reason’, the ‘Cosmos of Duty is thus really reduced to a Chaos: and the prolonged effort of the human

intellect to frame a perfect ideal of rational conduct is seen to have been foredoomed to inevitable failure'.

WhetherSidgwick regarded egoism as a matter of ethics or simply of rationality is hardly to the point; for him, the problem was to frame a rational way to live. He would have been dismayed to learn that the consistent (agent-relative) egoist would still challenge moral theorists at the close of the twentieth century.

In later editions and works, Sidgwick downplayed this dilemma, but his journal and letters reveal that he was always troubled by it. He had turned to ethics hoping to establish it as independently rational, perhaps a show of God's order; his inquiry drove him to the conclusion that ethics was incoherent unless the utilitarian could infer 'the existence of Divine sanctions' that would 'suffice to make it always every one's interest to promote universal happiness to the best of his knowledge'. Evidence for the personal survival of death might help, but by 1887 he was concluding 'that we have not, and are never likely to have, empirical evidence of the existence of the individual after death'. In a singular revelation, he explained that

> When I was writing my book on Ethics, I was inclined to hold with Kant that we must *postulate* the continued existence of the soul, in order to effect that harmony of Duty with Happiness which seemed to me indispensable to rational moral life. At any rate I thought I might *provisionally* postulate it, while setting out on the serious search for empirical evidence. If I decide that this search is a failure, shall I finally and decisively make this postulate? Can I consistently with my whole view of truth and the method of its attainment?
>
> (*Henry Sidgwick, A Memoir* 1906: 467)

His crisis of faith had proved enduring.

4 Epistemology and other works

Sidgwick also explored the epistemological issue of whether such a postulate was unwarranted. If physical science is indeed based on self-evident premises, then practical philosophy should seek such a foundation as well. However,

> We find that in our supposed knowledge of the world of nature propositions are commonly taken to be universally true, which yet seem to rest on no other grounds than that we have a strong disposition to accept them, and that they are indispensable to the systematic coherence of our beliefs, - it will be more difficult to reject a similarly supported assumption in ethics, without opening the door to universal scepticism.
>
> (*The Methods of Ethics* 1907: 509)

His intuitionism was scarcely unthinking or mystical - he was only converted to it by the claim that mathematics could find no other basis - and was based on the view that inferential knowledge presupposes significant non-inferential knowledge. And as such works as 'Criteria of Truth and Error' show, he rejected any 'simple infallible criterion' for ultimate knowledge and favoured a sophisticated fallibilist criterion for 'the humbler task' of 'excluding error'. For this, he advanced a threefold test: intuitive or Cartesian verification (clarity and certainty on careful examination), discursive verification (system and coherence) and ecumenical verification (consensus). The second test, he allows, 'is of special and pre-eminent importance', since 'the ideal aim of philosophy is systematization - the exhibition of system and coherence in a mass of beliefs which, as presented by Common Sense, are wanting therein', but, he adds, 'the special characteristic of *my* philosophy is to keep the importance of the others in view'.

Sidgwick has been cast as both an early practitioner of Rawlsian reflective equilibrium and a prescient critic of it, but such attempts to dress his moral methodology for contemporary debates often read him selectively and out of his historical context. He was moved by the intellectual, cultural and political tensions of the Victorian era; religious scepticism, moral scepticism and the threat of egoism in theory and practice came to form an unholy trinity against which he would contend in one arena after another. Even *The Methods* does not fully convey the persistence and ingenuity with which he engaged 'the deepest questions of human life' or the way in which his meta-ethics were at once intuitionist and fallibilist, commonsensical and dialectical.

Indeed, Sidgwick's work is rarely appreciated even as a comprehensive account of utilitarianism, covering political, legal and economic theory. *The Principles* gives a penetrating treatment of distributive justice from the utilitarian standpoint, and *The Elements* and *The Development of European Polity* carry the classical tradition far

beyond the simplicities of Austinian jurisprudence and ahistorical Benthamism, with a complex approach to the art of politics that balances analytic, historical and comparative methods. Such works reveal how, for Sidgwick, egoism was hardly a potentially cogent alternative for reformulating morals and politics, but was rather the view capable of inspiring most of what he found politically abhorrent: class or party conflict at home and neo-Machiavellianism in foreign policy.

In the end, Sidgwick's inquiries into epistemology and politics were, in his eyes, no more successful than his inquiries into religion, ethics and psychic research. Yet beyond his enduring accomplishments in clarifying utilitarianism and advancing substantive moral and political theory, it is perhaps the very tension between his subtle, penetrating scepticism and his longing for a rational faith and morality that make him one of the most fascinating representatives of his age.

BART SCHULTZ

List of works

The Sidgwick Papers, Wren Library, Trinity College, Cambridge, form the most extensive collection of original manuscript materials, but there are many other archival resources. The most comprehensive edition of Sidgwick's works, including all of his major works (with both the first and seventh editions of *The Methods*) and a wide range of his previously unpublished lectures and correspondence, is a database: (1997) 'The Complete Works and Select Scholarly Correspondence of Henry Sidgwick', ed. B. Schultz, Past Masters series, Charlottesville, VA: InteLex Corporation.

Sidgwick, H. (1870) *The Ethics of Conformity and Subscription*, London: Williams & Norgate.(This extremely important pamphlet marksSidgwick's first serious attempt to show how common-sense morality is incomplete and requires something like utilitarianism.)

Sidgwick, H. (1874) *The Methods of Ethics*, London: Macmillan; later edns, 1877, 1884, 1890, 1893, 1901, 1907. (Sidgwick's masterpiece, in which classical utilitarianism is given its most sophisticated formulation and reconciled with common-sense morality, though not with egoism. *The Methods* set the agenda for much of the substantive ethical theory and metaethics of the twentieth century. Changes made for the second and third editions were also published separately as supplements. Sidgwick wrote a number of commentaries on his book, including 'Some Fundamental Ethical Controversies' *Mind* 56 (1889); 'Prof. Calderwood on Intuitionism in Morals' *Mind* 4 (1876); and 'The Establishment of Ethical First Principles' *Mind* 13 (1879).)

Sidgwick, H. (1883) *The Principles of Political Economy*, London: Macmillan; later edns, 1887, 1901.(Sometimes dismissed as inappreciative of the marginalist revolution, Sidgwick's political economy was in fact informed by the work ofJevons, Marshall and Edgeworth, and his discussion of distributive justice and the role of the state provides an essential complement to the arguments of *The Methods*.)

Sidgwick, H. (1885) *The Scope and Method of Economic Science*, London: Macmillan. (Sidgwick's presidential address to the Economic Science and Statistics section of the British Association is a clever exposition of the limits of *laissez-faire* and the absurdities of the grandiose sociologies of Comte andSpencer (reprinted in *Miscellaneous Essays*).)

Sidgwick, H. (1886) *Outlines of the History of Ethics for English Readers*, London: Macmillan; later edns, 1888, 1892, 1896, 1902, 1931.(May well remain the best work of its kind; with succinctness and accuracy,Sidgwick surveys the entire range of philosophical ethics from its origins down to his own time.)

Sidgwick, H. (1891) *The Elements of Politics*, London: Macmillan; later edns, 1897, 1908, 1919; student edn, ed. B. Schultz, Cambridge: Cambridge University Press, 1998.(Sidgwick's second most important book, this massive volume provides another vital complement to *The Methods* by setting out Sidgwick's utilitarian politics and distinguishing his analytical approach from that of Bentham,Austin and the Mills. The student edition contains helpful secondary material, as well as new primary sources.)

Sidgwick, H. (1898, 1909) *Practical Ethics: A Collection of Addresses and Essays*, London: Swan Sonnenschein. (Essays and addresses delivered before various 'Ethical Societies' which aimed at 'the intelligent study of moral questions with a view to elevate and purify social life'. 'The Ethics of Religious Conformity' and 'Clerical Veracity' show the significance of this issue in Sidgwick's life and thought.)

Sidgwick, H. (1902) *Lectures on the Ethics of T.H. Green, H. Spencer and J. Martineau*, ed. E.E. Constance Jones, London: Macmillan.(Sidgwick came to think that *The Methods* did not do enough to address critically the transcendentalist and evolutionist positions, and this posthumous work thus provides a useful supplement to

The Methods by giving detailed criticisms of key representatives of these schools as well as further material on Martineau.)

Sidgwick, H. (1902) *Philosophy, Its Scope and Relations*, ed. J. Ward, London: Macmillan. (A succinct, precise articulation of his epistemology and its bearing on cognate fields of inquiry, mainly psychology, history and sociology.)

Sidgwick, H. (1903) *The Development of European Polity*, ed. E.M. Sidgwick, London: Macmillan.(A lucid historical survey of political doctrines, this posthumous volume provides the inductive, historical approach to politics that Sidgwick regarded as a necessary supplement to the analytical and deductive approach of *The Elements*.)

Sidgwick, H. (1904) *Miscellaneous Essays and Addresses*, ed. E.M. Sidgwick and A. Sidgwick, London: Macmillan.(Contains many ofSidgwick's best short works, including discerning literary studies of Clough andShakespeare, sober critiques of Arnold and perfectionist educational theories, various probing assessments of socialism, and a witty essay on 'Bentham and Benthamism'.)

Sidgwick, H. (1905) *Lectures on the Philosophy of Kant and Other Philosophical Lectures and Essays*, ed. J. Ward, London: Macmillan.(Contains some of Sidgwick's most significant metaphysical and epistemological work, and conveys some sense of his plan for his projected study of 'Kant and Kantism in England'. Includes 'Criteria of Truth and Error'.)

Seeley, J. (1896) *Introduction to Political Science*,ed. H. Sidgwick, London: Macmillan.(In editing the work of his colleague Seeley, an ideologue of British imperialism, Sidgwick perhaps unwittingly demonstrated the severe limitations of academic Victorian political theory.)

Schultz, B. (1996) 'Sidgwick, Henry', *Dictionnaire d'éthique et de philosophie morale*, ed. M. Canto-Sperber, Paris: Presses Universitaires de France, 1391-99.(A short but up-to-date introduction that both surveys Sidgwick's philosophy and points to his larger cultural significance, including his connections to such controversial figures as J.A. Symonds and F.W.H. Myers.)

Schultz, B. (1998) *Eye of the Universe: Henry Sidgwick and the Victorian Quest for Certainty*.(The only comprehensive treatment of Sidgwick's practical and theoretical philosophy, this book brings out the overall unity of Sidgwick's writings and the central role of scepticism and the dualism of practical reason in his life and work.)

Sidgwick, E.M. and Sidgwick, A. (1906) *Henry Sidgwick, A Memoir*, London: Macmillan.(The essential

biographical treatment, with a good bibliography; Sidgwick's widow and brother drew from his letters and journal, though they excluded excessively technical or personal material.)

Williams, B. (1982) 'The Point of View of the Universe: Sidgwick and the Ambitions of Ethics', *Making Sense of Humanity*, Cambridge: Cambridge University Press.(A wonderful introduction to Sidgwick, with a penetrating critical overview that gives special currency to the interpretation of Sidgwick as a 'Government House' utilitarian, but compares him favourably to Moore.)

Siger of Brabant (*c*.1240-*c*.1284)

Born probably circa *1240 in the Duchy of Brabant, Siger of Brabant studied philosophy in the arts faculty at the University of Paris and became regent master there in the 1260s. Various positions which he defended were included in Bishop Etienne Tempier's condemnations of 1270 and 1277, and he appears to have fled France when cited to appear before the French inquisition. He probably spent his final days in Italy, and died there before November 1284.*

As a professional teacher of philosophy, Siger regarded it as his primary mission to lecture on Aristotle and other philosophers and to present their views on the points at issue. Early in his career he defended some of the positions condemned by Bishop Tempier, but after 1270 he often nuanced his exposition of such views by noting that he was only presenting the views of the philosophers or of Aristotle, or that he was proceeding philosophically in these discussions. Often regarded as a leading Latin 'Averroist', he agreed with Averroes that there is only one human intellect, though he eventually reversed his view on this. His personal philosophy is strongly Aristotelian, but with various elements derived from Neoplatonism.

On the relationship between essence and existence in created beings, Siger denies that existence is something added to a thing's essence and holds that the existence of such entities belongs to their essence. He holds that one can demonstrate God's existence, but insists that Aristotle's physical argument for a First Mover must be completed by metaphysical argumentation. While denying that human beings in this life enjoy any direct knowledge of the divine essence, he seems open to Averroes' view that they can reach some knowledge thereof.

1 Life and works

Siger studied philosophy in the arts faculty at the University of Paris and became regent master in that faculty in the 1260s, perhaps *circa* 1263-5. Some of his views were included in a condemnation of thirteen propositions by Etienne Tempier, Bishop of Paris, in December 1270, and many more were included in Tempier's much broader condemnation of 219 propositions on 7 March 1277. Little is known about Siger's final years, but it is certain that in November 1276 he and two colleagues from the arts faculty were cited to appear before the French inquisition in January 1277. Apparently he and the others had already departed from France. He probably spent his final years in Italy and died some time before November 1284, murdered perhaps by a secretary. Although his name has long been associated with the radical Aristotelian movement in the arts faculty at Paris known by some as Latin 'Averroism' (see Averroism), he was never found guilty of heresy. Scholars have been intrigued by the fact that Dante Alighieri places him in Paradise, and has Thomas Aquinas introduce him.

Most of his surviving writings date from after 1270. Many of his works were reports taken down by others at his lectures, although some of these were later revised by Siger. Other works were originally composed by Siger himself, and some of these were probably based on prior scholarly disputations. A number are commentaries on works by Aristotle, or in one case, on the *Liber de causis*, written in the form of questions occasioned by the text (see Liber de causis).

2 Philosophy and religious belief

By Siger's time at Paris, the faculty of arts had become in fact a faculty of philosophy. This was owing in large measure to the recovery in Latin translation in the twelfth and thirteenth centuries of a large amount of philosophical literature of non-Christian origin originally written in Greek or in Arabic (see Translators). There had been initial reservations and even prohibitions early in the thirteenth century on the part of Church authorities at Paris against incorporating some of this newly available material into teaching in the arts faculty at the University. By 1255, however, the situation had changed to the point where the statutes for that faculty required students to read all the known works of Aristotle. Thus Siger regarded it as his primary mission to lecture on Aristotle and the other philosophers, and gave great weight to them.

Siger did this with such enthusiasm in two early works that some of his positions alarmed Bishop Tempier and were condemned in 1270. Thus in his *Quaestio utrum haec sit vera* he had accepted the eternity of the human species (and hence of the world) (see Eternity of the world, medieval views of), and in his *Quaestiones in Tertium De anima (Questions on Book III of Aristotle's On the Soul)*, the view associated with Averroes that the human

intellect is only one for the entire human race and exists apart from individual human beings (see Ibn Rushd). Particularly offensive to ecclesiastical authorities was the implication following from this that individual souls are not immortal (see Soul, nature and immortality of the).

In addition to Tempier's condemnation of these views, Thomas Aquinas sharply attacked the Averroistic and Sigerian defence of the unicity of the intellect in his *De unitate intellectus*, also of 1270. In subsequent works, when dealing with theologically sensitive issues, Siger became more circumspect and struggled to find a satisfactory resolution for the faith-reason problem. When dealing with points defended by Aristotle or Averroes or other philosophers which contradict Christian teaching, he often remarks that he is simply presenting such positions as the view of the philosophers, or according to the mind of the philosophers, or that he is speaking philosophically. In his final works, especially his *Quaestiones super Librum de causis (Questions on the Liber de causis)*, he moves still further in the direction of religious orthodoxy. In sum, while he never works out a fully satisfactory solution to the faith-reason problem, he appears to be sincere in his repeated protestations of religious belief and in his gradual movement toward more orthodox positions. At the same time, along with other colleagues in his faculty, especially Boethius of Dacia, he strongly defends the autonomy of philosophy within its own sphere, and the right of the philosopher, even though Christian, to draw conclusions from philosophical principles wherever they may lead. If these conclusions contradict religious belief, the Christian, being aware of the fallibility of human reason, should regard the teachings of faith as true. Siger does not defend the 'double-truth theory', according to which two contradictory propositions, one taught by philosophy and one taught by faith, could both be true at the same time (see Aristotelianism, medieval).

3 Metaphysics: the science of being as being

Siger is familiar with Aristotle's description in *Metaphysics* IV of a science that studies being as being and his contrast between this and more particular sciences which study the attributes of only particular parts of being. Siger also recalls Aristotle's presentation of three theoretical sciences in *Metaphysics* VI, physics, mathematics, and a divine science that studies separate and immobile (and divine) entities (see Aristotle). Avicenna denies that God can be regarded as the subject of this science, for he maintains that it belongs to metaphysics and not to physics to demonstrate God's existence. Since no science can demonstrate the existence of its subject, the subject of metaphysics is not God, but being as being (see Ibn Sina). Averroes affirms that it belongs to physics to demonstrate the existence of the First Mover or God, and that in referring to being as being as the subject of metaphysics, Aristotle really means that its subject is the primary instance of being, or God (see Ibn Rushd). In agreement with Avicenna, Siger holds that the subject of metaphysics is not God but being as being. However, he adopts an intermediary position on the issue of a physical or metaphysical proof of God's existence. The middle term used by Aristotle to prove God's existence in his *Metaphysics* is taken from his *Physics* (see God, arguments for the existence of).

4 Essence and existence

Much contested during Siger's time and thereafter was the issue of the relationship between essence and existence in created entities (see Existence). It was generally granted that they are identical in God. To account for the metaphysical structure of finite beings, Aquinas defends a composition of two distinct principles in such beings, an essence and a corresponding act of being (*esse*), often referred to by others as existence. Giles of Rome defends a seemingly more extreme version of this approach, and by 1276 Henry of Ghent sharply criticizes the real distinction between essence and existence, especially as presented by Giles; he postulates an 'intentional' distinction between them, that is, one that is less than real but more than purely mental.

In his *Quaestiones in Metaphysicam (Questions on the Metaphysics)* Siger asks whether in caused beings existence (*esse*) belongs to their essence. Against this claim he cites Boethius and Avicenna, and then as a leading critic of distinction between them, Averroes. Among contemporaries he presents Albert the Great as holding that existence is added to a thing's essence, and rejects this position. Siger presents as intermediary the view of Aquinas (in the latter's commentary on the *Metaphysics*) that existence is something added to a thing's essence, which does not belong to its essence and yet is not an accident but is, as it were, 'constituted' from the principles of the essence. Siger agrees with Aquinas that existence is not an accident, but complains about the way he formulates his position. For Siger, if existence belongs to a thing it must either be a part of that thing's essence, like matter and form, or something composed of those principles, or an accident. For Aquinas to say that it is added to the essence

without being any of these is for him to postulate a fourth nature among entities. Siger concludes that the existence of such entities belongs to their essence and is not something superadded. The terms which he now uses to signify essence and existence, ‘thing’ (*res*) and ‘existing entity’ (*ens*), do not signify different intentions but rather one and the same essence in different ways, one as potentiality (*res* = essence), and the other as actuality (*ens* = existing entity).

In responding to various arguments he had offered for real distinction between essence and existence, Siger notes that one especially moved Aquinas. Everything other than the First Being (God) must be composed. Because created pure spirits lack matter-form composition, they must be composed of essence and *esse*. To this Siger proposes two responses, though he does not assert the first definitively. First, it is enough to say that things other than God recede from him as pure actuality and are multiplied by approaching potentiality. This suffices to distinguish them from God without postulating different ‘essences’ within them. Second, even if one concedes Aquinas’ claim that to be distinguished from God created entities must somehow be composed, Siger finds it sufficient to appeal to substance-accident composition in created spirits. Even in them, there is a distinction between their substance and the intelligible species they use in thinking.

Interestingly, in his final work, *Quaestiones super Librum de causis (Questions on the Liber de causis)*, while discussing the kind of infinity enjoyed by the First Cause, Siger notes that in created spiritual entities existence (*esse*) is not limited by matter. Yet their existence is limited to their nature which receives it and is related to it as potentiality to actualization. Perhaps Siger now accepts Aquinas’ position on essence and the act of being.

5 Philosophical knowledge of God

Reference has been made to Siger’s insistence on incorporating Aristotle’s physical argument for a First Mover into metaphysical argumentation for God’s existence. For Siger, one cannot stop with a purely physical proof but must in metaphysics establish the existence of a supreme being which is unique, and which is the cause of being for all other entities. At different points in his *Quaestiones in Metaphysicam* he attempts to show that the First Mover is the creative cause of all other entities, including separate - that is, immaterial - substances. He also offers a series of arguments to show that there is only one first and uncaused cause (see Causation).

Presupposed for all his reasoning from effects to God as the first cause is Siger’s conviction that in this life human beings do not enjoy a direct knowledge of God’s essence. However, on one occasion in his *Quaestiones in Metaphysicam*, Siger comments favourably on Averroes’ view that human beings can arrive at some kind of knowledge of the divine essence. Siger himself here suggests that one who is truly expert in philosophy may be able to form an adequate idea of the divine essence. Also in his *Quaestiones super Librum de causis* he offers a series of arguments for and another series against the claim that the essence of the First Cause can be grasped by the human intellect. Unfortunately, his resolution of this question is missing from the text.

6 Procession of created reality from God

In his *De necessitate et contingentia causarum (On the Necessity and Contingency of Causes)*, Siger presents God as the immediate, necessary and eternal cause of the first intelligence, but as only the mediate cause of other effects. He supports this by appealing to the Neoplatonic axiom that from the one simple being (God) only one thing can proceed immediately. This view is at odds with traditional Christian belief both in affirming the eternal existence and the necessary production of various created realities, and in denying that God is the immediate creator of anything but the first intelligence. However, Siger also states twice in the course of his discussion that this is so according to the mind of the philosophers. Hence he may not have adopted this as his own position, although he does offer a sympathetic presentation of necessary emanation in one version of his *Quaestiones in Metaphysicam*. However, he clearly rejects the theory of mediate emanation or creation in his *Quaestiones super Librum de causis*.

7 Eternity of the universe

While their religious faith required Christian participants in this discussion to believe that the world began to be, much disagreement existed concerning whether this could be demonstrated philosophically. Bonaventure, at least as he is usually interpreted, defends this possibility. Aquinas denies that human reason can prove this and in his final treatment of the issue goes so far as to hold that an eternally created world is possible, philosophically

speaking. As already noted, in a work written before 1270, Siger defends the eternal existence of the human race. After the condemnation of 1270, when he presents argumentation for an eternal world or some eternally produced creature, he usually qualifies this by saying that this is so according to the mind of Aristotle or according to the mind of the philosophers and is careful not to defend the eternity of the world in his own name. Like Aquinas, he denies that human reason can prove that the world began to be (see Eternity of the world, medieval views of).

8 Unicity versus plurality of the human intellect

In his *Quaestiones in Tertium De anima* from the 1260s, Siger defends the view that there is only one separate intellect (including both the agent and the receiving or possible intellect) for the entire human race. The agent and possible intellects are two powers of one separate substance, and not two separate substances, as Averroes holds in his Long Commentary on the *De anima*. After the condemnation of 1270 and Aquinas' attack that same year, Siger deals with this issue very carefully. In his *De anima intellectiva (The Intellective Soul)* of *circa* 1273, after much discussion he declares himself unable to resolve this issue on purely philosophical grounds. He concludes that in such a matter one must follow the teaching of faith. In his final work, his *Quaestiones super Librum de causis*, he strongly argues on philosophical grounds that the intellective soul is a perfection of each individual human body, and that it is multiplied as are human beings themselves. His position is now perfectly orthodox.

Signposts Movement

*The symposium Signposts (*Vekhi*, sometimes translated* Landmarks*), published in 1909, was a* succès de scandale *which provoked a long debate of extraordinary intensity and scope on the nature and outlook of the Russian intelligentsia. The discussion continued after the 1917 Revolution among intellectuals in exile, and was resumed in Russia with the republication of the volume in the Gorbachev era.*

The contributors to Signposts were the philosophers N.A. Berdiaev (1874-1948), S.N. Bulgakov (1871-1944) and S.L. Frank (1877-1950); M.O. Gershenzon (1869-1925), a well-known critic and historian of literature; A.S. Izgoev (pseudonym of A.S. Lande, 1872-1935), a journalist active in the liberal Constitutional Democratic (Kadet) Party; B.A. Kistiakovskii (1868-1920), a specialist in constitutional law; and P.B. Struve (1870-1944), an eminent economist and editor, and a member of the Kadet Party's Central Committee. They argued that the 1905 Revolution had revealed the despotic potential in the intelligentsia's traditional materialist faith, and urged it to re-examine its values, which were based on a misunderstanding of human nature and threatened the existence of Russian culture.

The shock caused by the volume owed much to the fact that, unlike most of the intelligentsia's critics, the authors were not of the political right. The majority were former Marxists who had moved to forms of liberalism based on idealist positions in philosophy. But although many intelligentsia groups were also reassessing their values in the wake of the 1905 Revolution, for political reasons liberals closed ranks with the left in an overwhelming condemnation of Signposts as a betrayal of the cause of freedom. The famous Signposts debate (which was pursued in exile after 1917 as a discussion on the meaning of the Russian Revolution) was not a dialogue, but rather a succession of dogmatic professions of faith by mutually hostile political groups. Western historians have commonly stressed the symposium's significance as a prophetic indictment of Russian radical messianism from the standpoint of liberal pragmatism. But Signposts was not an ideological unity: as well as its dominant liberal Westernism it contained a strong strand of nationalistic messianism which had affinities with traditions on both the Russian left and the right. In this respect the volume reflects a fundamental tension in Russian thought between dogmatic utopianism and radical humanism.

1 From Marxism to idealism

Signposts' critique of the intelligentsia's outlook was grounded in the revival of metaphysical idealism in Russia at the beginning of the twentieth century. A major part in this was played by Struve, Berdiaev, Bulgakov and Frank, who had been leading exponents of Marxism in Russia in the 1890s, stressing its superiority over previous radical ideologies because of its 'scientific' demonstration of the historical inevitability of Russia's progression through capitalism to socialism. But, influenced by German Marxist revisionism, they began to lose faith in the predictive powers of Marx's revolutionary dialectic, and came to believe that the phenomenal world of law and necessity did not exhaust reality: there was also an inner world of goals and ideals. In 1901 a long preface by Struve to Berdiaev's *Sub''ektivizm i individualizm v obshchestvennoi filosofii (Subjectivism and Individualism in Social Philosophy)* outlined the general position on which all four were then converging as a result of their critique of the empirical and logical defects of deterministic materialism: a Kantian dualism that placed human goals and values in a transcendental realm, the source of the categorical imperative that the individual be regarded always as an end in himself and never as a means (see Kant, I. §9; Neo-Kantianism, Russian §5). They argued that in their pursuit of material goals the Russian radical intelligentsia had ignored mankind's metaphysical thirst for good, truth and beauty, and neglected what should be the ultimate aim of the fight for progress: the creation of a new human type, spiritually reborn, the bearer of ideal values.

In finding the positivist and materialist tenets of the Russian radical tradition inadequate as explanations of the world or guides to action, the four thinkers represented a widespread mood that found expression in the Russian Religious and philosophical renaissance and the cultural ferment of the 'Silver Age' (see Russian Religious-Philosophical Renaissance). In 1903 they contributed with eight other writers to the symposium *Problemy idealizma (Problems of Idealism)*, which sketched out idealist positions in the fields of ethics, sociology, the philosophy of history and law, in which to ground a systematic defence of the proposition that the individual was not just a cog in society but the source of its values. The contributors stressed the symposium's practical

purpose: like the new movements in literature and the arts, it was a response to a ‘striving for moral renewal’ among large numbers of the intelligentsia who believed that commitment to narrow political ideologies had stunted their personal growth and distorted their moral vision: the ’new man’ of the future, they hoped, would be a many-sided ’integral personality’, morally, intellectually and aesthetically developed. But while some contributors held that such a type would possess an ‘integral worldview’, in which knowledge and faith would be harmonised in the perception of the historical process as a movement to a transcendent goal, others were moving towards a humanistic idealism incompatible with a dogmatic metaphysics. The former included Berdiaev and Bulgakov, the latter Struve and Frank. Their diverging paths would lead to irreconcilable positions in *Signposts* on the question of the goals of progress in Russia and the intelligentsia’s role in their attainment.

2 Utopianism versus humanism

In his book *Sub’’ektivizm i individualizm v obshchestvennoi filosofii*, Berdiaev declared the need for ’an organically whole, positive view of the world; at this historical moment scepticism can only serve reactionary purposes’ (1901: 24). He and Bulgakov both believed that disenchantment with the millenarian promises of Marxism had left a vacuum that must be filled by a new faith to inspire the fight against autocracy. They found the source of this faith in the messianic vision of Vladimir Solov’ëv, who was a major influence on the revival of idealism in Russia at that period. Solov’ëv taught that alienation and social conflict were the results of the divorce of reason from religious faith. The spiritual unity of the psyche would be restored only when philosophy, science and theology were united in the pursuit of the supreme aim of knowledge: an understanding of the ’total-unity’ of all existence through communion with its source, God (the Absolute) to which it is destined to return. The historical process was a movement to this final goal: an era when mankind would live an ’integral life’ within an ’integral society’ - a utopia both humanistic and theocratic, uniting East and West, Church and state. Like the Slavophiles, Solov’ëv believed that Russia’s destiny was to fulfil a religious mission: to be the first bearer of the new life among mankind (see Slavophilism; Solov’ëv, V.S.).

Berdiaev and Bulgakov saw no contradiction between their defence of the individual’s right to self-direction against the encroachments of collectivistic social doctrines and their belief in a form of historical determinism that drew heavily on Solov’ëv. In *Problemy idealizma* Bulgakov defines historical progress as the march of the Absolute towards its goal. All nations and individuals have their particular historical mission, ’foreordained in the moral world order’, which can be discovered by consulting conscience, the voice of the Divine Will within each individual. Bulgakov’s religious evolution was already leading him away from historical to theological concerns (he became an Orthodox priest in 1918). Berdiaev on the other hand was involved in all aspects of the Russian cultural renaissance. He was active in discussions in which representatives of the Church and the intelligentsia sought a *rapprochement* on questions of morality and culture, and until 1908 was part of the circle of Symbolist writers and religious thinkers grouped around D.M. Merezhkovskii and his wife, the poet Zinaida Gippius. He shared their enthusiasm for Nietzsche’s ideas and adopted Merezhkovskii’s theory of the imminent coming of a ‘New Religious Consciousness’ based on a ’Third Testament’ which would teach a morality reconciling Christ and AntiChrist, the flesh and the spirit, Nietzschean self-affirmation and Christian brotherhood (see Nietzsche: impact on Russian thought §1). He greeted the 1905 Revolution as an apocalypse that signalled the advent of a religious utopia, but, disillusioned by its failure to achieve the goal of political liberty, concluded that the attainment of freedom was not possible in the material world, and broke with Merezhkovskii’s group, taking up a stance of spiritual revolt against the irredeemable philistinism of human societies, a position much influenced by Nietzsche, and which he described as mystical anarchism. He warned the intelligentsia that Russia’s cultural backwardness could not be overcome by a historical leap - a view that was hard to reconcile with the belief that he also expressed at that period, that Russia was destined to bring about a universal spiritual regeneration by assimilating Western culture and combining it with Orthodox spirituality.

Berdiaev and Bulgakov were intransigent utopians who (as their memoirs reveal) had been attracted to Marxism by its promise of a wholly emancipated mankind. In contrast, Struve records that he had been drawn to Marx’s economic analysis by the light it shed on the practical problems of achieving civil and political liberties in an undeveloped economy. In 1900 he moved from Social Democracy to liberalism, and in 1906 became a member of the Central Committee of the newly formed Kadet Party and subsequently editor of a leading liberal journal, *Russkaia mysl’ (Russian Thought)*. He was followed to liberalism by Frank, who had become a close friend. Both regarded their political allegiance as an expression of their religious humanism, basing their defence of gradualism

and compromise on their belief in the inseparability of the material and spiritual elements in human creativity, and its roots in the continuity of national life. They stressed the interdependence of freedom and culture, which they defined as the embodiment of eternal values in the economic and social structures, artefacts and everyday activities of historical existence. They regarded the Russian left's faith in the principle of destruction as anti-cultural and thereby antilibertarian, and devoted their journalism between 1905 and the First World War principally to a campaign against all forms of radical and religious messianism that, in the expectation of an historical leap to a state of ideal freedom, ignored the importance of historical continuity and of the everyday tasks of social construction and cultural creation.

3 *Signposts*

While the four ex-Marxists often aired their differences in print, they were agreed in holding the intelligentsia principally to blame for the anarchy and destruction of the 1905 Revolution and its failure to attain its objectives. For this reason the literary historian M.O. Gershenzon invited them to contribute to a symposium on that theme, together with two liberals concerned with similar issues, B.A. Kistiakovskii (who had contributed to *Problemy idealizma*) and A.S. Izgoev.

In his introduction to *Signposts* Gershenzon outlines the reasons for the project. The intelligentsia's traditional values had been tested by the Revolution and found wanting. The volume's aim was to contribute to the process of self-examination that had ensued among the intelligentsia by offering its own diagnosis of their malaise. Despite differences of principle among the authors, they shared a common platform: recognition of the theoretical and practical primacy of the individual's inner spiritual life over the external forms of community. They believed that the intelligentsia's outlook, which rested on the opposite principle - recognition of the unconditional primacy of social forms - was erroneous in theory and harmful in practice.

Although the essays were written without prior consultation among the authors, they had a number of themes in common, chief among which was a critique of the intelligentsia's moral relativism and its utilitarian approach to all values as means to political ends. Kistiakovskii points to the traditional contempt of Russian radicals for legal principles, which they perceived as impediments to revolutionary change. Berdiaev notes their indifference to philosophical truths which could not be used for social purposes. Frank defines their outlook as 'nihilistic moralism': a rejection of objective and universally binding moral standards combined with a deification of the subjective interests of the masses which (identified with the goals of a specific class or party) had been invoked to sanction violence and criminality during 1905. Gershenzon pointed out that the intelligentsia's preoccupation with revolutionary agitation had led them to neglect the skills and capacities needed for the task of social construction. Izgoev noted that the supreme criterion of virtue among young radicals was readiness to die for the cause; Bulgakov argued that the left's idolatrous worship of the revolutionary hero was the root cause of its preference for extreme positions over compromise in all cases. But he and Berdiaev differed from the other contributors in discerning positive qualities in the intelligentsia's maximalism, arguing that its ascetic hostility to bourgeois culture and values expressed an unconscious religious thirst for the Kingdom of God on Earth which had close affinities with the religious and cultural messianism of the Slavophiles, Dostoevskii, and Vladimir Solov'ëv. They placed their hopes for Russia's political and cultural progress on a future synthesis of the religious and secular traditions of Russian thought whereby the intelligentsia, having renounced its atheism, would apply itself to the elucidation of Russia's spiritual mission in the world.

Struve's essay, however, rejects the theory of the intelligentsia's unconscious religiosity as a myth. He and Frank unambiguously condemn its ideological intransigence, in which they see the seeds of despotism and mob rule. Struve argued that the intelligentsia's traditional opposition to the state had led it to ignore the problem of education in politics and social reform: it had appealed to the instincts and passions of the masses in 1905 instead of using the concessions forced out of the government as a means of schooling the people in the habits of democracy. Frank attacks the cult of 'simplicity' common to Russian radicalism and Tolstoism: a puritanical hostility to all cultural values that were alien to the traditional life of the Russian peasant. Berdiaev and Bulgakov discerned an admirable otherworldliness in the intelligentsia's aversion to the bourgeois culture of the West; Struve and Frank looked forward to its embourgeoisement, when it would cease to exist as a separate cultural category with its own traditions and fanatical faiths, and would turn its attention from the redistribution of material goods to the creation of cultural values.

As Struve remarked after *Signposts'* publication, it reflected the traditional division in Russian thought between Westernizers and Slavophiles. (The latter included Gershenzon who, unlike the other contributors, had little interest in politics but shared the Slavophiles' concern with spiritual 'integrality'.) *Signposts* pointed simultaneously in opposing directions.

4 The debate

The symposium was the sensation of the year. It was pronounced on by public figures and passionately discussed in newspapers and journals throughout the Russian Empire. It generated three counter-symposia; meetings and speeches were devoted to it, and it soon ran into five editions.

To the authors' embarrassment, the volume was fulsomely praised by the conservative right which interpreted it as a political attack on the left. The great majority of the intelligentsia took the same view, representing the authors as the government's agents or its unconscious tools. In the words of the Socialist Revolutionary leader Viktor Chernov *Signposts* was 'the most reactionary book of the decade'. A Kadet symposium on the volume argued that while some of its criticism was valid, the intelligentsia's shortcomings were a consequence of Russia's economic backwardness and the Signposts authors themselves were not immune from its diseases. Among Russian writers only the Symbolist poet and novelist Andrei Belyi and the essayist Vasilii Rozanov publicly expressed solidarity with its critique of the values of the left, whose battle against metaphysics, aesthetics and religion had, in Rozanov's view, resulted in the loss of its 'spiritual sight'.

The intelligentsia's overwhelming hostility to *Signposts* has been cited by historians as evidence of its dogmatic adherence to its traditional revolutionary mystique. But the experiences of 1905 had led to a widespread questioning of that mystique in the radical movement, notably among the leadership of the Socialist Revolutionary Party, who had begun a fundamental re-examination of their moral assumptions, while writers sympathetic to the left, such as D. Merezhkovskii, commented on the role of religious and philosophical ideas in the transformation of its outlook. The closing of the intelligentsia's ranks against *Signposts* was due to the belief that their criticism came from a hostile camp and would strengthen conservative political forces. In the Kadets' case there was a tactical reason (the desire to preserve a coalition with the left) for distancing themselves from *Signposts*. The party's leader, Miliukov, even found it necessary to undertake a lecture tour around Russia for the purpose of attacking the volume: this did not prevent Lenin from labelling *Signposts* 'an encyclopedia of liberal apostasy'.

The *Signposts* authors failed to spark off a discussion of the intelligentsia's self-image on their own terms; but the volume may be seen as part of a wider mood of self-examination among the Russian intelligentsia which sprang from the philosophical and religious revival of the early twentieth century, and which, in the last decade before the Revolution, was reflected in a growing moral opposition to the outlook of the Bolsheviks from other parties on the left.

5 The sequels

In 1918, as the Bolshevik dictatorship began to hunt down its critics, while civil war raged in the south of Russia and the countryside was ravaged by anarchy and famine, *Signposts*' predictions of a national catastrophe seemed tragically prophetic. Struve, living clandestinely in Moscow, conceived the idea of a sequel which could discuss the causes and meaning of the 1917 Revolution. He brought together all the *Signposts* authors except Gershenzon and Kistiakovskii, and six others, including P.I. Novgorodtsev, who had been the editor of *Problemy idealizma*, and the Symbolist poet Viacheslav Ivanov. All had been prominent in Russian intellectual life before the Revolution.

The new symposium's title, *Iz glubiny (Out of the Depths)*, was taken from the 130th Psalm. It was confiscated before it could be distributed and only two copies found their way to the West. It was virtually unknown until it was reprinted in Paris in 1967. The authors interpret the Revolution as a vindication of *Signposts'* warnings. The essays fall into two main categories: those primarily concerned with what Struve called the 'ultimate religious questions' of human existence, including such topics as the 'Russian soul'; and those that focus on more concrete social and political issues. The two approaches are exemplified in the contributions of Berdiaev and Struve respectively. Struve points to the contradiction between socialism's rational theory and destructive practice, while Berdiaev contends that the Revolution revealed a dark side of the Russian soul: the anarchic nihilism first

diagnosed by Gogol’ and Dostoevskii.

All the contributors express the hope for a spiritual rebirth of the Russian people based on national and religious values, but are unspecific on the form this should take. Berdiaev was then engaged in developing a philosophical interpretation of the Russian Revolution as the prelude to the end of European civilization, which would be apocalyptically transformed into a new universal culture which Russian thinkers like himself (whose spiritual make up, he believed, represented a synthesis of East and West) were destined to reveal to the world. In his book *The Philosophy of Inequality*, published in Berlin in 1923, he would attack the ’tyranny of democracy’, and call for ’total freedom’, which he admits is unrealizable on earth. In *Out of the Depths* as in *Signposts*, the aims of religious utopians conflict with those of liberal humanists, such as Struve, who defends the right to property and economic liberty and the principles of individual responsibility and initiative, although (as in earlier writings on this theme) he emphasizes the importance of a strong and unified state as the guardian of the national culture.

In 1921 the debate over *Signposts* was taken up in emigration with the publication in Prague of a volume of essays entitled *Smena vekh (Change of Signposts)*, the manifesto of a short-lived movement later known as ’National Bolshevism’. Its proponents, mainly former Kadets who claimed to be inspired by the nationalist strand in *Signposts*, called for reconciliation with the Bolsheviks on the grounds that in its sweeping destruction the Revolution had been an authentically Russian phenomenon, an expression of the people’s instincts. A counter-symposium, *O smene vekh (On Change of Signposts)* (1922), whose authors included Izgoev, appeared inside Russia, protesting against what they saw as this group’s distortion of the principles of *Signposts*: as the embodiment of revolutionary nihilism, Bolshevik ideology could not be the basis of a new national culture. Struve (by then in emigration) also strongly repudiated the new movement as intellectually and morally contemptible.

This marked the end of the public debate over *Signposts* in emigration, although the work frequently figured in émigré literature. Its central themes were echoed in the work of two *Signposts* authors in particular: as editor of a succession of émigré periodicals, Struve devoted much of his writing to the question of the meaning of the Russian Revolution, while Berdiaev (who as a philosopher became the best known of the *Signposts* authors in the West) produced interpretations of Russian thought for a Western audience.

Mention of *Signposts* in official Soviet historiography was confined to a recapitulation of Lenin’s attack on it, but in the post-Stalin period Russian dissidents who were rediscovering pre-revolutionary Russian philosophy and religious thought found its critique of the intelligentsia’s values highly relevant to their own time. In 1974 the exiled Solzhenitsyn, with a number of intellectuals who were still in Russia, published a collection of essays modelled on *Signposts* whose title *Iz-pod glyb (From under the Rubble)* was a phonetic echo of the Russian words for *Out of the Depths*. Although differing from *Signposts* on some issues, the collection cites it as a vision of the future which sheds light on the spiritual bankruptcy of the Soviet elite.

One of the first fruits of the new press freedoms under Gorbachev was the republication of *Signposts* and *Out of the Depths*. The lively interest of post-Soviet Russian intellectuals in *Signposts* (which has since gone into several reprints) suggests that it may now play a role in the intelligentsia’s self-examination that was denied it in 1909. Recent commentaries on *Signposts* in the West have linked it with Mikhail Bakhtin’s subsequent critique of dogmatic thought, as part of a minority current in the Russian intellectual tradition which refused to regard all moral questions as political ones, and which is enjoying a significant revival today.

Silvestri, Francesco (1474-1528)

*A Thomist philosopher and theologian, Silvestri composed, along with Aristotelian commentaries and polemical works, a vast commentary on Aquinas' Summa Contra Gentiles which, from the first, has been recognized as its classic exposition. Silvestri imitated the method (*expositio formalis*) of Cajetan's commentary on Aquinas' Summa Theologiae, but disagreed with Cajetan on key points of Thomistic doctrine and proposed interpretations generally closer to the letter of Aquinas. Chief among these are the doctrines of analogy, abstraction and the rational demonstrability of the soul's immortality.*

Francesco Silvestri was born in Ferrara and, hence, is commonly known as Ferrariensis (or as Francis Sylvester of Ferrara). He entered the Dominican Order in 1488 and completed his initial studies in Bologna in 1497. In 1498 he was appointed lector in Mantua. From 1503-8 he lectured in Milan and from 1509-11 in Bologna. He spent 1511-3 as bachelor of the *Sentences* in Milan and subsequently returned to Bologna where he graduated as master of theology in 1516. He was then elected prior of the convent in Ferrara, and also taught at the university. In 1519 he was appointed inquisitor in Bologna and in 1521-4 he was regent master of the Dominican *studium generale* there. In 1524 he was elected prior of the convent in Bologna and, soon after, Pope Clement VII named him vicar general of the order. He was elected master general at the general chapter held in Rome in 1525 and continued in this office until his death.

Silvestri's doctrine of analogy is presented in his commentary on Aquinas' *Summa contra gentiles* as a critical supplement to that of Cajetan (§2). Unlike the latter, Silvestri is more concerned with accurate exegesis of Aquinas' text than the refutation of Scotism and is, accordingly, more attuned to the determination of analogy's logical structure than to its metaphysical implications. Starting from Aquinas' affirmation that analogy is the predication of terms according to an order of priority and posteriority (see Aquinas §9), he makes a clear distinction between such an order (1) as operative in the psychological process of naming, and (2) as holding in reality and representing the relative positions of things in the hierarchy of being.

Two features are essential to every instance of analogy: first, secondary analogates bear some kind of reference to the primary analogate (*ordo ad unum*); second, the proper notion (*ratio propria*) of the primary analogate enters the definition of secondary analogates. From this follows a division of analogy foreign to Aquinas: analogy may be founded on the relation (or resemblance) which holds between either a plurality of things and one other thing (*duorum ad tertium*) or between one thing and another (*unius ad alterum*). The latter kind is further divided into analogy founded on a direct, fixed relation between one thing and another (analogy of proportion) and analogy founded on an indirect, loose relation between one thing and another (analogy of proportionality). Unlike Aquinas and Cajetan, Silvestri distinguishes between these two latter types of analogy in psychological rather than mathematical terms. The analogical predication of names of God and creatures cannot be of the kind *duorum ad tertium* because there is no prior 'third thing' to which both God and creatures are related (or that both God and creatures resemble), so as to justify the imposition of common terms. It can only be the analogy of proportionality that permits one to talk meaningfully about God and that, unlike analogy of proportion, safeguards the divine transcendence (see Language, Renaissance philosophy of §4).

Silvestri proposed a personal theory of abstraction in a critique of Cajetan's explanation (*In Contra Gentiles Commentaria* II c.77). He argues that Cajetan attributes to the phantasm features of the intelligible object (universality, immateriality), transforming it into a direct object of intellection and rendering the agent intellect redundant. For Silvestri the agent intellect performs a 'radical and fundamental' illumination. It acts upon both the phantasm and the possible intellect, and acts in conjunction with the imagination (*phantasia*) to produce the impressed intelligible species.

Silvestri is original on several other epistemological and metaphysical issues. The possible intellect has the capacity to form a proper concept of the singular sensible object in addition to, and after, the formation of the universal concept which represents the common nature. Numerical multiplication is possible within species of immaterial substances. The individuation of material substances is effected by matter in so far as it is quantified by determined dimensions.

Silvestri has been considered fundamentally a disciple, albeit at times critical, of Cajetan. He should rather be counted a member of the Bolognese Thomist school founded by Peter of Bergamo (d. 1482) and represented during the early sixteenth century by such figures as Sylvester Prierias (1456-1527), Chrysostom Javelli (1470-1543) and Bartholomeo de Spina (d. 1545). Generally opposed to Cajetan on speculative issues, their differences came to the fore during the Pomponazzi affair (see Pomponazzi, P. §2). This is the context of Silvestri's own defence of the rational demonstrability of the soul's immortality. Especially in need of correction is the explanation of the Bolognese Thomists' opposition to Cajetan (and Pomponazzi) in terms of an inability to distinguish between philosophy and Aristotelianism (Laurent 1938; Nardi 1958). This distinction is, in fact, stressed by all of them, including Silvestri.

Simmel, Georg (1858-1918)

Georg Simmel was a prolific German philosopher and sociologist, who was one of the principal founders of sociology in Germany. His philosophy and social theory had a major impact in the early decades of the twentieth century, both among professional philosophers and sociologists and within the cultural and artistic spheres. This is true of his foundation for sociology, his philosophy of art and culture, his philosophy of life and his philosophy of money. His thought ranged from substantive issues within the philosophical tradition to a concern with the everyday world and its objects.

Although he insisted on many occasions that he wished to be recognized as a philosopher and despite his extensive philosophical writings, Simmel is today still largely known as one of the founders of German sociology at the turn of the nineteenth century.

Simmel taught at Berlin University from 1885 to 1914 until he obtained a chair in philosophy at Strasbourg University, which he held until his death. Although he studied philosophy (under Eduard Zeller and Friedrich Harms), history and ethnology at Berlin University, Simmel regarded his most significant teacher to be the *Völkerpsychologist* Moritz Lazarus. Simmel's writings, especially in the early period, manifest a wide range of influences: Darwin, Herbert Spencer, Gustav Fechner, Lazarus, Kant, Schopenhauer and others. Not surprisingly he was subsequently categorized as a positivist, pragmatist, Neo-Kantian, the 'German Bergson', a philosopher of life and a relativist.

His doctoral dissertation of 1881 on Kant's monadology indicated the commencement of a critical confrontation with Kantian philosophy, but despite his later contact with leading Neo-Kantians, such as Heinrich Rickert, it is not easy to subsume Simmel's philosophy under that of the Neo-Kantian tradition (see Neo-Kantianism, §2). His early monographs displayed seemingly diverse theoretical interests. *Über sociale Differenzierung (On Social Differentiation)* (1890) contained Simmel's first attempt to ground sociology methodologically as an independent discipline, as well as applications of his sociological method. *Die Probleme der Geschichtsphilosophie (The Problems of the Philosophy of History)* (1892) argued against the existence of universal historical laws, but it was its second (totally rewritten) edition of 1905 which had a significant impact upon methodological discussions within the social sciences on historical method and problems of interpretive understanding. The two-volume *Einleitung in die Moralwissenschaft (Introduction to Moral Science)* (1892-3) was devoted to rejecting universal ethical concepts and principles as an a priori formalistic grounding for moral philosophy in favour of a critical, psychological, sociological and historical investigation of the diversity of ethical norms in their everyday practice.

If several of these early works did not receive substantial acclaim, the same cannot be said of Simmel's most sustained philosophical study *Philosophie des Geldes (The Philosophy of Money)* (1900). If, as stated in its preface, one of philosophy's aims is to bring together the fragments of knowledge into a totality, then money serves as an instance for the presentation of relations between the most diverse and often fortuitous objects and for the possibility of discovering in each of the details of life the totality of its meaning. The philosophy of value appropriate for money as the universal equivalent of all values is some version of relativism or relationism. Simmel's wide ranging philosophy of money makes important contributions to the theory of value, to the philosophy of social action within a means/end framework, to a theory of the individual person and individual freedom, and to the aesthetics of modern society. Money as symbol of the eternal flux of interrelations between the most diverse phenomena serves to generate a theoretically grounded relativism. Many of Simmel's contemporaries viewed this rich synthesis as a philosophy of specifically 'modern' times and its author as possessing an instinct for the philosophical exploration of modernity.

In the period after publication of *The Philosophy of Money*, Simmel intended working on a volume on the philosophy of art and aesthetics, a project which, despite an extensive number of essays in this area on landscape, the picture frame and other aesthetic themes, never came to fruition. However, he did publish his highly popular and influential introductory lectures on *Kant* (1904) and on *Schopenhauer und Nietzsche* (1907) - both volumes serving as testimony to the impact of these philosophers upon Simmel's own development.

The work which did have a major influence was his *Soziologie (Sociology)* (1908), the culmination of more than a decade's concern with explicating his version of sociology. There, numerous substantive applications of his sociological method were preceded by Simmel's most elaborated foundation of sociology as the study of the forms of sociation and social interaction. The concept of interaction or reciprocal effect (*Wechselwirkung*) which pervades his philosophical writings lies at the centre of his foundation of sociology, focusing on the analysis of forms that social relations take. Human sociation is created in social interactions and Simmel's programme for sociology opens up the study of any and all forms of sociation as a basis for understanding how society is possible. This accounts for the extensive breadth of Simmel's sociological - and philosophical - investigations, an insistence upon the fundamental interrelatedness of all phenomena, a relational sociology and philosophy.

The necessary abstraction and separation of form from content which his sociology requires is itself indicative of more fundamental separations pervading his philosophy as a whole, but most fully developed in his later writings, namely between subjective and objective culture and between life and form. Explorations of the dialectical relationship between subjective and objective culture are at the heart of Simmel's philosophy and sociology of culture; the investigation of the opposition between life and form is at the centre of his philosophy of life (*Lebensphilosophie*). (See Lebensphilosophie).

Simmel's theory of culture radicalized the widening gap between subjective, individual culture and a more rapidly expanding objective culture - both material and non-material. This problematic of cultural alienation, in which human subjects must still realize themselves within an objective culture from which they are estranged, had a significant influence upon cultural and social theorists (especially in the tradition of critical theory). At the same time, essay collections such as *Philosophische Kultur (Philosophical Culture)* (1911) revealed a concern to develop not merely a philosophy of *culture* but also a *philosophical* culture capable of analysing this and other problematics.

Simmel's later writings also developed a philosophy of life grounded in the opposition of life and form in which life as a dynamic dimension struggled against rigidified form in a dialectical tension. This suggested affinities with Bergson's vitalism (see Bergson, H.-L.), but also significantly influenced contemporary artistic movements, notably German Expressionism.

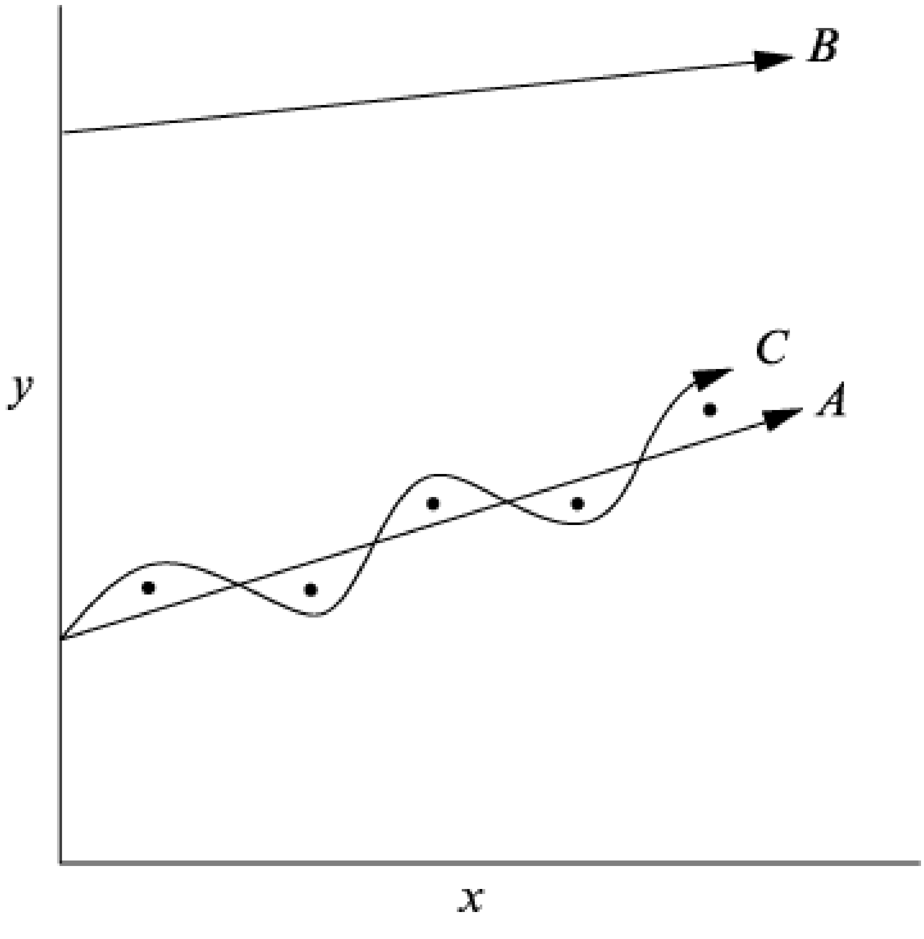
Simplicity (in scientific theories)

In evaluating which of several competing hypotheses is most plausible, scientists often use simplicity as a guide. This raises three questions: what makes one hypothesis simpler than another? Why should a difference in simplicity make a difference in what we believe? And how much weight should simplicity receive, compared with other considerations, in judging a hypothesis' plausibility? These may be termed the descriptive, the normative, and the weighting problems, respectively. The aesthetic and pragmatic appeal of more simple theories is transparent; the puzzle is how simplicity can be a guide to truth.

1 Curve-fitting, parsimony and unification

Considerations of simplicity play a role in the *curve-fitting problem*, depicted in the figure. Suppose a scientist wants to discover what general relationship obtains between the independent variable *x* and the dependent variable *y*, and pursues this question by gathering a set of observations, each of which corresponds to a point.



What role might the data play in evaluating different competing hypotheses, each of which corresponds to a curve? If observational error is impossible, then any curve that fails to pass exactly through the data points must be false. However, error is always possible. This means that the true curve may fail to pass exactly through the data points. How, then, are the data to be used?

The standard scientific procedure is to use the concept of 'goodness-of-fit'. Consider Curve *A*. For each data point, compute the squared distance from the observed *y*-value to the *y*-value that Curve *A* predicts. The 'sum of squares' (SOS) measures how far the curve is from the data. If SOS measures how well the data support the curve in question, then the data in the figure support Curve *A* better than they support Curve *B*.

The rationale for SOS as a measure of evidential support is not far to seek. Curves that are close to the data are more likely, in the technical sense defined by R.A. Fisher (1925). Curve *A* is more likely than Curve *B* (given standard assumptions about the probability of error) because *A* confers on the data a higher probability than *B*

does: $\mathrm{P}(\mathrm{Data} \mid \mathrm{Curve}\ A) > \mathrm{P}(\mathrm{Data} \mid \mathrm{Curve}\ B)$. It is important in this context not to confuse likelihood and probability. The conclusion is not that *A* is more probable - that is, that $\mathrm{P}(\mathrm{Curve}\ A \mid \mathrm{Data}) > \mathrm{P}(\mathrm{Curve}\ B \mid \mathrm{Data})$.

Although likelihood as measured by SOS helps discriminate between Curve *A* and Curve *B*, it says nothing concerning how *A* compares with Curve *C*. They have the same SOS values. It is at this point that simplicity is said to be relevant. Curve *A* is smooth and Curve *C* is bumpy. Curve *A* seems more simple. If simplicity guides our judgements about which curve is more plausible, we will conclude that Curve *A* is superior to Curve *C*, given the data at hand.

If curve-fitting is subject to the twin criteria of goodness-of-fit and simplicity, the descriptive, normative, and weighing problems must all be addressed. The last of these is quite fundamental. In general, the goodness-of-fit of a hypothesis can be improved by making it more complicated. In fact, with *n* data points, *perfect* goodness-of-fit (an SOS of zero) can always be secured by a polynomial of degree *n* (that is, an equation of the form $y = a_1 + a_2x + a_3x^2 + \ldots + a_nx^{n-1}$). If there are just two data points, a straight line will fit them perfectly; if there are three, a parabola can be found with an SOS of zero, and so on. The practice of science is to view goodness-of-fit as one consideration relevant to evaluating hypotheses, but not the only one. The problem is to understand that practice.

Simplicity considerations play a role in other inferential contexts. Ockham's razor, the principle of parsimony, says that hypotheses that postulate fewer entities, causes or processes are better than hypotheses that postulate more. In addition, the preference for simpler hypotheses finds expression in the idea that a unified theory that covers two bodies of phenomena is sometimes more plausible than a disunified theory that treats them as separate and independent. An adequate account of the role of simplicity in curve-fitting should bring in its wake an understanding of the value that science seems to place on parsimonious and unified theories.

2 Bayesian approaches

Bayes' theorem shows how the posterior probability $\mathrm{P}(H \mid O)$ of a hypothesis - the probability that *H* has, given that the observation *O* has been made - is related to the probability $\mathrm{P}(H)$ the hypothesis had prior to the observation: $\mathrm{P}(H \mid O) = \mathrm{P}(O \mid H)\mathrm{P}(H)/\mathrm{P}(O)$ (see Probability, interpretations of §5; Statistics §2). When two hypotheses, H_1 and H_2, are evaluated in light of the observations *O*, the theorem entails that $\mathrm{P}(H_1 \mid O) > \mathrm{P}(H_2 \mid O)$ if and only if $\mathrm{P}(O \mid H_1)\mathrm{P}(H_1) > \mathrm{P}(O \mid H_2)\mathrm{P}(H_2)$. That is, if H_1 has the higher posterior probability, then it must have the higher likelihood or the higher prior probability (or both).

Let us apply the Bayesian framework to the curve-fitting problem represented in the figure. How could Curve *A* have a higher posterior probability than Curve *C*, relative to the data depicted? There are two possibilities to explore, and one of them will not help. We have already noted that the two curves have the same likelihoods. This means that a Bayesian must argue that Curve *A* has the higher prior probability.

However, if prior probabilities are to be assigned to curves, a problem arises. The straight lines in the *x*-*y* plane are not denumerable. Apparently, they are equally simple. If their prior probabilities are to reflect just their simplicity, then they must be assigned the same prior probability - namely, zero. But hypotheses assigned a prior probability of zero cannot increase in probability when favourable evidence is obtained.

An alternative approach would be to assign probabilities, not to specific curves, but to families of curves. For example, the straight lines comprise a family of curves (LIN), each having the form $y = a_1 + a_2x$, while (PAR) is the family of parabolas, each having the form $y = a_1 + a_2x + a_3x^2$. In these equations, the a_i terms are *adjustable parameters*; members of the family are specified by assigning values to these parameters.

If the assignment of prior probabilities is limited to a denumerable set of such families, with simpler families receiving higher values, it is possible to construct an infinite series of positive prior probabilities that converges on a sum that is not greater than unity. This is the approach that Harold Jeffreys (1957) adopts.

It is important to take care that the families in this series are disjoint. For example, since (LIN) is included in (PAR), (LIN) cannot have a higher probability. With nested families of curves, more complex families have higher probabilities. One solution is to define the family (PAR′), which is the subset of (PAR) in which all adjustable parameters are nonzero. No contradiction ensues if one assigns (LIN) a higher prior than (PAR′).

However, a problem now arises, one that concerns Bayesianism in general. If prior probabilities merely report an agent's subjective degrees of belief, then there is no reason why we should assign (LIN) a higher prior than (PAR′) rather than doing the reverse. And once this normative question is addressed, it must puzzle the Bayesian why (LIN) should be more probable than (PAR′). After all, (LIN), in effect, sets the parameter $a_3 = 0$, while (PAR′) stipulates that $a_3 \neq 0$. What could show that the former is more probable than the latter?

Bayesians may reply that their goal is to describe the practice of science, not to justify it. Another option is to abandon the goal of analysing the complexity of families of curves and to focus exclusively on some denumerable set of curves with no adjustable parameters. A third would be to theorize about the likelihoods of families of curves as a measure of their simplicity (Rosenkrantz 1977).

3 Popper

Karl Popper (1959) turns the Bayesian approach on its head. For him, the goal of science is to find highly *im*probable hypotheses. Hypotheses should be valued for their falsifiability - for their saying more, rather than less. Popper conjoins this requirement with the idea that we should reject hypotheses that have been falsified. So the two-part epistemology he proposes is that we should prefer hypotheses that are unfalsified though highly falsifiable. This means that we should prefer (LIN) over (PAR) if neither has been falsified by the data. (LIN) is more falsifiable, says Popper, because at least three data points are needed to falsify it; for (PAR) to be falsified, at least four observations are required.

One problem for Popper's proposal arises when it is applied to equations that contain no adjustable parameters. If we consider, not (LIN) and (PAR), but some specific straight line and some specific parabola, then each can be falsified by a single observation. All specific curves are equally falsifiable.

A further limitation in the Popperian approach should be noted. A purely deductivist methodology cannot explain why scientists reasonably decline to reject curves that fail to pass exactly through the data points. The three curves in the accompanying figure are all 'falsified' by the data. However, as Popper sometimes intimates, a more adequate assessment of the fit of hypotheses to data is afforded by the concept of likelihood; rather than considering the yes/no question of whether a hypothesis has been falsified, we need to consider the quantitative issue of the degree to which a hypothesis says that the observations were to be expected. It is arbitrary to impose on that continuum a cut-off point that separates the stipulated categories of 'falsified' and 'unfalsified'. However, once likelihood is substituted for the concept of deductive falsification, the weighting problem arises as a significant issue.

4 Akaike

The statistician, H. Akaike and his school have developed a set of theorems that show how the predictive accuracy of a family of curves may be estimated (1973).

The predictive accuracy of a family reflects how well it does in predicting new data when its parameters are estimated from an old data set. Consider (LIN) as an example. First find the member of (LIN) that best fits the available data, D_1. This straight line is the likeliest member of that family; call it $L(\text{LIN})$. Then obtain a new set of data, D_2, from the true (and unknown) underlying curve, and measure how well $L(\text{LIN})$ fits D_2. Now imagine repeating this process, first finding the best fitting member of (LIN) with respect to one data set and then using that curve to predict new data. The average performance of (LIN) defines its predictive accuracy, which also might be termed its closeness to the truth.

Akaike's theorem says that the following provides an *unbiased* estimate of the distance from the truth of family *F*:

$$\text{Estimate (Distance from the truth of family } F) = \text{SOS}[L(F)] + 2k\sigma^2 + \text{constant}$$

Here *k* is the number of adjustable parameters in *F*, and σ^2 is the error variance - the degree of dispersion of observations around the true curve. The third addend disappears when hypotheses are compared with each other, and so may be ignored.

The second addend in the displayed equation gives simplicity its due: the complexity of a family is measured by how many adjustable parameters it contains. It is important to note that the number of adjustable parameters is not

a syntactic feature of an equation. Although the equations ‘ $y = ax + bx$’ and ‘ $y = ax + bz$’ may each seem to contain two parameters (*a* and *b*), this is not the case. The former equation can be *reparameterized*. Let $a' = a + b$; now the first equation can be restated as ‘ $y = a'x$’. In fact, the first equation contains one parameter, while the second contains two.

The second term in Akaike’s theorem, besides adverting to the number of adjustable parameters, also mentions the error variance. When this variance is large, this second term plays a larger role in estimating the family’s distance from the truth; when observations are largely free of error, it makes only a negligible contribution. Simplicity cannot matter when observational error is impossible; it matters more and more as the data become noisier.

Akaike’s theorem applies to one of the most famous examples of the role of simplicity considerations in hypothesis evaluation - the dispute between Copernican and Ptolemaic astronomy. In Ptolemy’s geocentric model, the relative motion of the earth and the sun is replicated within the model for each planet; the result is a system containing a very large number of adjustable parameters. Copernicus decomposed the apparent motion of the planets into their individual motions around the sun and a *common* sun-earth component, thereby drastically reducing the number of adjustable parameters. In *De revolutionibus*, Copernicus argued that the weakness of Ptolemaic astronomy derives from its failure to impose principled constraints on the separate planetary models. Thomas Kuhn (1957) and others have claimed that the greater unification and ‘harmony’ of the Copernican system is a merely aesthetic feature. The Akaike framework offers a quite different diagnosis: since the Copernican system fitted the data then available about as well as the Ptolemaic system did, Akaike’s theorem entails that the former had an *astronomically* superior degree of estimated predictive accuracy.

Simplicity, divine

To be complex is to have many parts. To be simple is to have few. Theists of all religious traditions have asserted that God is completely simple - that is, has no parts of any sort. A contemporary statement of this doctrine of divine simplicity would add that God is identical with each of his intrinsic attributes. Thus if God is omnipotent and omniscient, for example, then he is identical with omnipotence and omniscience (and so these attributes are also identical). The doctrine's popularity across traditions may rest on theists' shared convictions that God is the ultimate reality, perfect, and creator of all that is not himself, and on the fact that many theists have thought that each of these claims entails the doctrine of divine simplicity. It may also rest on strands of mystical experience common to many traditions.

The doctrine has played an important part in ontological arguments for the existence of God because of its assertion of the identity of God with God's nature (if the latter in some sense exists, so must the former). Indeed, divine simplicity is near the conceptual core of classical theism; it is one chief reason classical theists think God immutable, impassible, timeless and wholly distinct from the universe. Many who oppose divine simplicity do so because of these other doctrines it entails. Other recent critics have charged that divine simplicity makes God a mere abstract entity or requires him to have all his attributes necessarily or all contingently.

1 The popularity of simplicity

The claim that God is simple asserts that God has no parts of any sort. Different thinkers have had different inventories of kinds of part. But the doctrine of divine simplicity claims that *whatever* kinds of part there are, God lacks them. (This is why Trinitarian Christians have been able to accept divine simplicity: whatever the Trinity's persons are, they are not parts of God (see Trinity).) So thinkers' beliefs in different kinds of part need not give them different versions of divine simplicity. Medieval friends of divine simplicity treated intrinsic accidental attributes and essential attributes distinct from their subject as among its parts (see, for example, *Summa theologiae* Ia 3, 3 and 6). So the doctrine of divine simplicity led them to say that God lacks these, that is, that God is not distinct from his essential attributes and has no intrinsic accidents. Given divine simplicity, then, if God is essentially omnipotent, God is identical to omnipotence. 'Omnipotence' *seems* to pick out an essential attribute God has, but *really* refers just to God. Further, if God is essentially omniscient, God is identical to omniscience, and so omniscience is identical to omnipotence.

But there is a question as to how we interpret these attribute-identities. Most medieval thinkers before Duns Scotus held that, save for 'proper accidents' (of which a simple God has none), if necessarily whatever is *F* is *G* and whatever is *G* is *F*, *F*ness and *G*ness are identical. But these thinkers used a concept of necessity weaker than broadly logical necessity (see Knuuttila 1993). As they use the term 'necessary', it can be the case that necessarily whatever is *F* is *G* and vice versa even if it is *logically* possible that something be *F* but not *G*. On their modal views, then, it can be logically possible that something be *F* but not *G* and yet be the case that *F*ness and *G*ness are identical. So if pre-Scotus medieval philosophers say that intrinsic divine attributes are identical, they may make a weaker claim than we would make by these words. If *we* say that *F*ness is identical to *G*ness, we imply that nothing can be *F* but not *G*. If medieval philosophers who say that *F*ness is identical to *G*ness do not imply this, then our concept of identity may not correctly represent their claim. Thus medieval versions of divine simplicity may not identify all of God's intrinsic attributes, but only those *F*s and *G*s for which they would say that nothing can be *F* but not *G* or *G* but not *F*. So perhaps divine simplicity's medieval partisans would let God have logically contingent attributes distinct from his essence (Stump and Kretzmann 1985). Still, many medieval arguments which deny that God has intrinsic accidents work as well against the claim that God has logically contingent attributes (see, for example, *Summa theologiae* Ia, 3, 6). So it is likely that the modal theory medieval philosophers employ betrays their intent, and that they *meant* to identify God with all of God's intrinsic attributes.

Divine simplicity has been in the mainstream of Western theism at least since Aristotle (§16). It moved from Middle Platonism into Judaism through Philo of Alexandria. The doctrine entered Christianity through such Church Fathers as Athenagoras, Irenaeus and Clement of Alexandria (see Platonism, medieval §§1-2). It became orthodox in Augustine (§7) and reigned unchallenged through to the time of Duns Scotus. The key to Plotinus' theology, and so to the change from Middle Platonism to Neoplatonism, is his making divine simplicity the core of

his account of the One, the supreme God; as Stoicism and Epicureanism faded away, versions of Platonism embodying divine simplicity became the theology of late paganism (see Plotinus §3; Neoplatonism §3). Divine simplicity was the main point at issue in one of the earliest Islamic theological debates, that over the status of the divine attributes. This debate later became that between orthodox Islamic theologians and partisans of Aristotle, and so enlisted Ibn Sina, al-Ghazali and Ibn Rushd (see Islamic theology §3). Given the ties between medieval Arabic and Jewish philosophy, divine simplicity naturally became a prime topic of medieval Jewish theology as well. Mystics of all periods, East and West, have claimed divine simplicity as a direct deliverance of their experience.

2 The case for simplicity

One may well wonder why (save for mystical experience) theists of so many traditions and times concur in the doctrine of divine simplicity, or even care about so abstract a claim. One reason is that basic theistic intuitions seem to converge on divine simplicity. The intuition that God is the ultimate reality (see God, concepts of §1) suggests divine simplicity, for anything composed of parts (or having distinct attributes) is less basic than they and depends on them (*Summa contra gentiles* I, 18). The intuition that God is creator of all that is distinct from himself suggests divine simplicity, for if God was composed of parts or had essential attributes distinct from himself, these would be distinct from him, yet he could not have created them without creating himself. The intuition that God is perfect suggests divine simplicity, for (at least to classical theists) it suggests that God is maximally self-sufficient. Whatever has parts or essential attributes distinct from itself depends on these and so is less self-sufficient than a simple being.

A second reason for divine simplicity's popularity has been that it is a fertile source of further claims about God; it yields a strong, interesting theological theory. First, if God is simple, then:

(N) necessarily, whatever is God is simple.

For if God is simple, the attribute of being divine is identical to the attribute of being simple. (N) entails that whatever is God is:

Unique. There can be at most one God. For suppose that there are two simple beings, *A* and *B*. *A* and *B* must differ in some attribute, else they would be identical. So suppose that *A* and *B* differ in that *A* has and *B* lacks an attribute *F*. If *F* is the attribute of being simple, then if *A* and *B* are both simple, both *A* and *B* have it. But *A* and *B* *differ* in *F*. So *F* is not being simple. But then if *A* has *F*, *A* has two distinct attributes, *F* and being simple. Whatever has two distinct attributes is not simple; all of a simple being's attributes are identical, as all are identical with the simple being itself. Hence if *A* has *F*, *A* is not simple. So only *B* is simple. Thus there can be at most one simple being. So given (N), there can be at most one God: divine simplicity guarantees monotheism. This helped draw Jews and Muslims to divine simplicity, given their creedal emphasis that God is one; Maimonides was so enthusiastic as to argue that monotheism entails divine simplicity (see *The Guide for the Perplexed*). The tie to monotheism may also have commended divine simplicity to Trinitarian Christians facing charges of tritheism (see Monotheism).

Immaterial. Whatever has matter in its make-up contains that matter's parts. Divine simplicity thus guarantees God's complete distinctness from the universe, or his transcendence.

Immutable. Whatever changes becomes different in a part or attribute (else there was no change), yet is the same in some parts or attributes (else there was not change, but a thing's disappearing and being replaced by another). So what has no parts or distinct attributes cannot change (see Immutability §§1-2). Aquinas and many others argue that any immutable substance is:

Timeless. It has no past or future, its life neither containing nor located in any series of earlier and later events (*Summa theologiae* Ia, 9, 1 and 10, 2). So if this is right, divine simplicity entails timelessness (see Eternity).

If nothing created God, divine simplicity guarantees that God is:

A se. God is entirely independent. For if God has no parts or distinct attributes, nothing can make a causal contribution to his existence except by making him *ex nihilo*, or out of no prior material. If God is *a se*, he is:

Impassible. He is completely unaffected by other things. If other things affected God, putting him in a state *S*, God would depend on those things for *S* and so not be wholly *a se*. Further, given divine simplicity, God would be identical with *S*. So whatever caused *S* to exist would have caused God to exist.

Given appealing assumptions, divine simplicity entails that God is:

Necessarily existent. If he exists, he cannot fail to exist. Assume that:

(a) God exists,
(b) if *P* is actual, then necessarily, *P* is at least possible (the Brouwer axiom), and
(c) entities have attributes only if they actually exist.

Given (a) and (b), then necessarily, it is possible that God exists. On (c), if possibly God exists, this is because some entity has an attribute which makes this true: presumably because God's nature exists and is possibly exemplified. So given (a)-(c), necessarily, God's nature exists. On divine simplicity, God is identical to God's nature. So if God's nature exists necessarily, God exists necessarily. So given (b), (c) and divine simplicity, if God exists, God exists necessarily (see Necessary being §§1-2).

Divine simplicity explains the common theistic claim that God is present as a whole wherever he is present (see Omnipresence §4): what has no parts is present as a whole if at all. Again, given divine simplicity, God's psyche is peculiarly simple. This can help to explain God's moral perfection. Traditionally, this includes *impeccability*, or inability to sin (see, for example, *Summa theologiae* Ia, 25, 3 *ad.* 2). If God is simple and wants to do good, then God is impeccable. For given divine simplicity, all God's desires are identical with God's desire to do good. So if nothing can be both a desire to do good and a desire to do evil, God cannot have a desire to do evil. But his necessary omniscience guarantees that he cannot do evil through ignorance, and his necessary omnipotence guarantees that nothing can force him to do evil. So divine simplicity, a desire to do good, necessary omnipotence and necessary omniscience yield impeccability. Again, if God's psyche is simple, his knowing is identical to his willing. This generates appealing theories about God's relation to morality and modality (Mann 1989), as does divine simplicity's implication that God is identical to God's nature (Kretzmann 1983).

Divine simplicity implies all these conclusions, but most do not in turn entail divine simplicity. Thus divine simplicity is one of the strongest, most basic assertions of theologies in which it appears; it is near the conceptual roots of the classical theist's concept of God (see God, concepts of §6).

A third reason for divine simplicity's popularity has been its connection with efforts to prove God's existence. Historically, Aristotelians inferred divine simplicity directly from their cosmological arguments (for example, *Summa theologiae* Ia, 3, 1-7) (see God, arguments for the existence of §1). Given actualism, 'possibly God exists' entails 'God's nature exists', and given divine simplicity, God is identical to God's nature. So given divine simplicity plus actualism:

(P) 'possibly God exists' entails 'God exists'.

(P) is a key premise of many ontological arguments for God's existence (see God, arguments for the existence of §§2-3). Good prospects (as they thought) for proving a simple being's existence likely gave Western religious thinkers further reason to embrace divine simplicity; by so doing, they believed, they could help give theism rational warrant.

3 Challenges to simplicity

Islam rejected divine simplicity in reacting against Aristotelianism; some Jewish philosophers (for example, Crescas) also rejected it. Within Christianity, divine simplicity's first real challenge was Duns Scotus' positing of a 'formal distinction' between divine attributes, faculties, and so on. Other challenges arose in Leibniz, Spinoza, Hegel, and nineteenth- and twentieth-century theology. Some reject divine simplicity because it implies other doctrines they question: it has been a casualty in revolts against divine immutability, impassibility, timelessness and distinctness from the universe. Thus one must in part pursue the case against divine simplicity in cases against these other doctrines.

Recent discussion in analytic philosophy has focused on divine simplicity itself. Some philosophers (for example,

Plantinga 1980) reject divine simplicity on the grounds that since it entails that God is identical to God's attributes, it entails that God *is* an attribute, an abstract object. But this need not follow: it may follow only that the one thing which is both God and an attribute has divine attributes and also some attributes typical of abstract objects, a claim theists endorse anyway.

Some philosophers (for example, Morris 1985) raise a problem of modal uniformity: if all God's attributes are identical, God has all attributes necessarily or all contingently. But God seems to have both necessary and contingent attributes: he is necessarily omnipotent, but only contingently the creator of Adam (since he need not have created Adam). Perhaps divine simplicity need not face this problem; as we have seen, the medieval philosophers may not have meant to identify all of God's attributes. But if they did, advocates of divine simplicity can perhaps counter by distinguishing attributes from predicates. Even if God has just one intrinsic attribute, that attribute, coupled with God's *relations* to other things, may let God satisfy some predicates necessarily and others contingently. God necessarily satisfies '…is omniscient', because every possible world contains only truths God would know if he created that world. God contingently satisfies '…is Creator of Adam' because only in some possible worlds is there an Adam. The difference in modality rests on entities outside God and their relations to God.

If God cannot have logically contingent intrinsic attributes but has created Adam, it may follow that the inner intrinsic state of God by which he knows and has created Adam might instead have not known and not created Adam, without itself being intrinsically any different. Is this conceivable? Consider a complex entity consisting of God plus the world he makes. If this complex entity contains the world, it is different if the world is different, but it does not follow that God himself is different. On an 'externalist' view of divine mental content, this complex entity could be God's mind. On the more usual picture, God's mind is wholly internal to God, and a difference in God's mind is prior to and explains a difference in the world. On an 'externalist' picture of God's mind, a difference in God's mind *includes* a difference in the world, but may not include a difference in God himself. If divine intrinsic simplicity does preclude God's having logically contingent intrinsic attributes, perhaps its price is that we are always in God's mind.

Simplicius (*fl.* first half 6th century AD)

Simplicius of Cilicia, a Greek Neoplatonic philosopher and polymath, lived in the eastern part of the Roman Empire. He is the author of the most learned commentaries on Aristotle produced in antiquity, works which rest upon the accumulated accomplishments of ancient Greek philosophy and science. In them he gives numerous illuminating references and explanations that not only lead to a fuller understanding of Aristotle, but also allow one to reconstruct the history of the interpretation and criticism of Aristotelian doctrines in antiquity. The main principle that guides Simplicius' exegesis is the conviction that most Greek philosophers, including some Presocratics, can be brought into agreement with Neoplatonism. Simplicius adduces copious quotations to prove his point, thereby supplying us with substantial fragments from lost works of thinkers like Parmenides, Empedocles, Anaxagoras, Eudemus and the Stoics. A devout pagan, Simplicius sought to defend traditional Greek religion and philosophy against the oppressive dominance of Christianity. His commentaries have influenced the reception and interpretation of Aristotle's philosophy ever since.

1 Life and writings

The circumstances of Simplicius' life are largely unknown. He was probably slightly older than his great rival, the Christian commentator and theologian John Philoponus. Simplicius studied first at Alexandria under Ammonius, son of Hermeas, the influential philosophical head of the school there, and later under Damascius, the last head of the Neoplatonic school at Athens. The course of Simplicius' life and career underwent dramatic change in 529, when, in the wake of the empire's anti-pagan policies, the Emperor Justinian I closed the Athenian school of philosophy. During the crisis, seven Athenian philosophers, among them Simplicius, Damascius and Priscian, emigrated to Persia where Chosroës I enjoyed a reputation as a philosopher-king. Their sojourn was disappointing and brief. The philosophers left the Persian court when, in a peace treaty between Persia and Byzantium in 532, Chosroës' diplomacy secured them the liberty to live on Roman territory without fear of persecution, although they were presumably barred from public teaching. Arabic sources, in conjunction with inconclusive evidence in Greek texts, suggest however that some of them were active in the Mesopotamian town of Carrhae (Harran), a pagan stronghold near the Persian border. Whether Simplicius belonged to this group, or returned to Athens, or indeed went elsewhere, is a matter of considerable controversy (see also Aristotle Commentators).

Simplicius wrote his major works after the Persian adventure. With the exception perhaps of the relatively late commentary on Aristotle's *Categories*, these are pieces of scholarship to be read, rather than lectures delivered in class. There seem to be no further treatises extant in manuscript form. Works on Iamblichus and on Hermogenes' rhetoric are lost, and perhaps even a commentary on Aristotle's *Metaphysics*, which is referred to in the commentary on Aristotle's *On the Soul*. This latter work bears Simplicius' name, but is of inferior quality and has plausibly been attributed to Simplicius' contemporary Priscian. If this is correct, evidence for a *Metaphysics* commentary by Simplicius becomes slim.

2 Hermeneutics and ethics

Simplicius makes his hermeneutic position explicit in the commentary on the *Categories*, a set book for philosophical beginners. The scholars of the sixth century (Ammonius, Philoponus, Olympiodorus, Elias and Simplicius) all discuss, in the introductions to their lectures on the *Categories*, ten questions regarding Aristotle's philosophical corpus as a whole, its structure and its end. One of these questions concerns the qualifications and attitude of the proper exegete of Aristotle. The stock answer is that the interpreter, in addition to being knowledgeable, must strive to discern the truth and, if necessary, prefer it to Aristotle. Philoponus seems to have been the only one to put this maxim to practical use. Characteristically, Simplicius glosses over this requirement and emphasizes instead that rather than voice his own philosophical convictions the exegete should seek out the agreement between Plato and Aristotle. Likewise, the student should refrain from quibbling with Aristotle. Simplicius is convinced that the 'truth' can be found in the harmony of Plato, Aristotle and other inspired thinkers. Thus, he is prepared to accept doctrines on the basis of authority, especially if they can be shown to agree with the fundamental ideas of Neoplatonism (see Neoplatonism).

Simplicius' earliest surviving work, *On Epictetus' Manual*, is a commentary on the *Manual (Enchiridion)* of the Stoic philosopher Epictetus. In general, Neoplatonists scorned the materialist outlook of the Stoics (see Stoicism

§3). Stoic ethics, however, conforms to the lowest level of the Neoplatonic system of moral instruction, which requires the practice of, in ascending order, political, purificatory and contemplative virtues. In the Preface, Simplicius explains that Epictetus' aphorisms and maxims are beneficial to those who want their bodies and desires to be ruled by rationality. A training in the political virtues resulting in a moderation of one's emotions initiates the ascent of the embodied soul through philosophy. The aim is the pure contemplation of intelligible Forms. This separation of the soul from the concerns of the body is also the road to salvation, and Simplicius conceives of his works simultaneously as intellectual and spiritual exercises. In a political atmosphere that increasingly suppressed and eradicated the remnants of paganism, his commentaries also protested against what he perceived as the blasphemy of the new religion.

3 Physics

The text that exemplifies this aspect most clearly is the commentary on Aristotle's *On the Heavens*. In one respect, it is a scholarly exegesis of Aristotle's cosmological treatise, enriched with invaluable information on ancient astronomy. A prominent feature, however, is the polemic against the renegade John Philoponus, a Christian Neoplatonist trained in Alexandria. At the very time when the Athenian philosophers were struggling for survival, Philoponus launched an attack on the Aristotelian-Neoplatonic doctrine of the eternity of the world by rejecting, among other points, Aristotle's theory of the existence of a celestial fifth element, aether (*On the Heavens* I.2-4). In an unprecedented spirit of criticism, Philoponus called the cogency of Aristotle's reasoning into doubt and argued that the supra- and sub-lunary regions are in fact of the same corruptible nature. In his reply, Simplicius offers the last defence in antiquity of Aristotle's controversial theory of aether. However, in the course of his counter-attack Simplicius loses sight of the crucial point - Aristotle's postulate of a fifth elementary body that naturally displays circular motion. Simplicius interprets Aristotle as meaning something approximating Plato's theory (*Timaeus* 40a, 58c-d) that the heavens consist of a mixture of the purest grades of the four elements, in particular luminous fire (*On Aristotle's On the Heavens* 12.27-13.3; 85.7-15). Moreover, Simplicius holds that celestial motion is not caused by nature but rather by the agency of a celestial soul (78.17-80.13), a position Aristotle at one point explicitly rejected (*On the Heavens* II.1, but see also 285a29). Despite considerable reinterpretations such as these, the commentary turns into a grandiose reaffirmation of the divinity and eternity of the heavens and the universe as a whole. The sincere prayer to the creator-intellect with which Simplicius ends his work underscores the vital link, so characteristic of Neoplatonism, between philosophy and spirituality.

A less elevated work is the monumental commentary on Aristotle's *Physics*, which modern scholars have culled primarily for its invaluable reports and quotations from earlier philosophers, most importantly the Presocratics. Recent scholarship, however, has shown that here too Simplicius occasionally comes forward with original interpretations of fundamental concepts of Aristotle's natural philosophy. For example, ever since Plotinus (§4), many Neoplatonists had interpreted Aristotle's prime matter as incorporeal, formless and devoid of magnitude, an elusive entity capable of accepting the property of indefinite extension and thus becoming the substrate for all physical forms. In the sixth century, both Philoponus and Simplicius revised this idea and paved the way for a conception of matter as mass. Philoponus polemically rejected the notion of prime matter as incoherent and superfluous, positing three-dimensional extension as the lowest level of the physical world. Without entering into any kind of polemic, Simplicius chose to interpret the Aristotelian prime matter in a very similar way, calling it an extension and an indefinite diffusion (*Physics* commentary, 537.22-538.14).

This notion of prime matter is not easily distinguished from that of space. Like many thinkers before him, Simplicius finds fault with Aristotle's definition of a thing's place (*topos*) as the adjacent boundary of the containing body (*Physics* 212a2-6). However, he also rejects the notion of space (*chōra*) as empty extension, and in the so-called 'corollary on place' (*On Aristotle's Physics* 601-45) he conflates, much like Aristotle, the idea of 'extension' with that of 'location'. On the one hand, Simplicius speaks of place *qua* extended space as a substance that is both animate and immobile (623.19-21). On the other hand, he defines place as incorporeal but perceptible in bodies, an ordering of the position of each thing relative to others (642.14-21). Significantly, it is place that facilitates order in the physical universe, since it provides the physical images of the intelligible paradigms with structure and allows them to be similar to the paradigms (626.28-32).

A further example of Simplicius stepping beyond the bounds of mere exegesis is his discussion of time. Aristotle began his analysis in *Physics* (4.10) by presenting two arguments suggesting, paradoxically, that time is unreal.

The premises (1) that the past exists no longer, (2) that the future exists not yet, and (3) that the present, being an instant, cannot be considered a 'part' of time (for as the temporal analogue of a point, it cannot serve as a measure of any length of time) seem to entail the unreality of time. Moreover, the view of the present as an instant renders mysterious how the present ever ceases to exist, for this can neither take place *at* the present instant nor *at* some later instant. In the so-called 'corollary on time' (*On Aristotle's Physics* 773-800) Simplicius points out that Aristotle's paradoxes arise only if one regards as existent that which is in fact always and only in a process of becoming. He reiterates the view of Damascius that time does not exist in actuality, as a sensible object might exist, but that 'it has its being in becoming'. His solution that time is never actual, but always potential, may seem to yield too much to the claim that time is unreal. However, on Simplicius' Neoplatonic view, passing time is only an image of 'primary time', which is a stable intermediate between the fleeting time of the physical realm and unparticipated eternity (784.17-785.10).

4 Logic and mathematics

On Aristotle's Categories is probably the latest authentic work of Simplicius we possess. One question that particularly interested Neoplatonists was the subject matter, or *skopos*, of Aristotle's treatise: is it about words, things or concepts? (See Porphyry §2; Categories §1; Aristotle §7). Simplicius explains that the treatise concerns itself with human language and, more precisely, with its simple, primary and generic utterances (*phōnai*) in so far as they signify concrete objects (*pragmata*). It instructs us about such objects, but also about the concepts (*noēmata*) through which the utterances gain signification (*On Aristotle's Categories* 13.11-15). In the course of this study of language the soul is once again being prepared in an ideal way for its ascent to the noetic world.

Like most Neoplatonists, Simplicius had a keen interest in mathematics. *On Aristotle's Physics* contains an extensive discussion of geometry including an extract from Eudemus' *History of Geometry* concerning the quadrature of lunes by Hippocrates of Chios. These passages bear witness to the oldest Greek mathematical work and present important material for a reconstruction of the history of pre-Euclidean mathematics. Fragments of a commentary by Simplicius on the definitions, postulates and axioms of book I of Euclid's *Elements* are extant in Arabic.

5 Influence

Through his work, Simplicius shaped the reception and interpretation of Aristotle for centuries. The bibliographies of Ibn an-Nadim and Ibn al-Qifti show that his commentaries were at least partially known in the Arab world (see Aristotelianism in Islamic philosophy). The first Latin translations by Robert Grosseteste and William of Moerbeke date from the thirteenth century and had an immediate impact on Thomas Aquinas and his circle. Later, Simplicius is one of the pillars of Renaissance Aristotelianism (Galileo, in the *Dialogue*, names his Aristotelian straw man 'Simplicio'), and even today his work is indispensable for any serious student of Aristotle or the history of Greek philosophy.

CHRISTIAN WILDBERG

List of works

Simplicius (*c*.533) *On Epictetus's Manual*, ed. I. Hadot, *Simplicius - Commentaire sur le 'Manuel' d'Épictète. Introduction et édition critique du texte grec*, Leiden: Brill, 1996.(The volume includes a long general introduction to Simplicius as well as a good bibliography.)

Simplicius (*c*.536) *On Aristotle's On the Heavens*, ed. I.L. Heiberg, *Commentaria in Aristotelem Graeca VII*, Berlin: Reimer, 1894.(A commentary on Aristotle's cosmological treatise and vigorous defence of the pagan notion of the divinity of the heavens.)

Simplicius (after 538) *On Aristotle's Physics*, ed. H. Diels, *Commentaria in Aristotelem Graeca IX- X*, Berlin: Reimer, 1882-5; parts available in translation, as follows: B. Fleet, *Simplicius on Aristotle's Physics 2*, London: Duckworth, 1997; J.O. Urmson and L. Siorvanes, *Simplicius, Corollaries on Place and Time*, London: Duckworth, 1992; J.O. Urmson and P. Lautner, *Simplicius, On Aristotle on the Void*, London: Duckworth, 1994; D. Konstan, *On Aristotle Physics 6: Simplicius*, London: Duckworth, 1989; C. Hagen, *On Aristotle's Physics 7: Simplicius*, London: Duckworth, 1994; C. Wildberg, 'Simplicius, Against Philoponus on the Eternity of the World', in D. Furley and C. Wildberg, *Place, Void, and Eternity*, London: Duckworth, 1991, 95-134.(Diels gives Greek text only; the others are translations with notes.)

Simplicius (after 538) *On Aristotle's Categories*, ed. C. Kalbfleisch, *Commentaria in Aristotelem Graeca VIII*,

Berlin: Reimer, 1907; trans. and ed. I. Hadot, *Simplicius: Commentaire sur les Catégories*, Leiden: Brill, fasc. I and III, 1990, fasc. II, 1996; trans. *Simplicius, Commentaire sur le Catégories d'Aristote, traduction de Guillaume de Moerbeke*, ed. A. Pattin and W. Stuyven, *Corpus Latinum Commentariorum in Aristotelem Graecorum III*, Paris: Éditions Béatrice-Nauwelaerts, 1971.(The Hadot text contains French text with comments by different authors; the Patton and Stuyven text is the standard translation of the medieval Latin translation.)

Simplicius (*c*.540) *On Aristotle's On the Soul*, ed. M. Hayduck, *Commentaria in Aristotelem Graeca XI*, Berlin: Reimer, 1882; trans. in part, J.O. Urmson and P. Lautner, *Simplicius, On Aristotle's On the Soul 1.1-2.4*, London: Duckworth, 1995.(The authorship of this work is disputed, the date uncertain.)

Sin

The most archaic conception of human fault may be the notion of defilement or pollution, that is, a stain or blemish which somehow infects a person from without. All the major religious traditions offer accounts of human faults and prescriptions for dealing with them. However, it is only when fault is conceived within the context of a relationship to a personal deity that it makes sense to speak of it as an offence against the divine will. The concept of sin is the concept of a human fault that offends a good God and brings with it human guilt. Its natural home is in the major theistic religions of Judaism, Christianity and Islam.

These religious traditions share the idea that actual or personal sins are individual actions contrary to the will of God. In the Hebrew Bible, sin is understood within the context of the covenantal relation between Yahweh and his chosen people. To be in covenant with Yahweh is to exist in holiness, and so sin is a deviation from the norms of holiness. In the Christian New Testament, Jesus teaches that human wrongdoing offends the one whom he calls Father. The Qur'an portrays sin as opposition to Allah rooted in human pride.

According to Christian tradition, there is a distinction to be drawn between actual sin and original sin. The scriptural warrant for the doctrine of original sin is found in the Epistles of Paul, and the interpretation of Paul worked out by Augustine in the course of his controversy with the Pelagians has been enormously influential in Western Christianity. On the Augustinian view, which was developed by Anselm and other medieval thinkers with considerable philosophical sophistication, the Fall of Adam and Eve had catastrophic consequences for their descendants. All the progeny of the first humans, except for Jesus and his mother, inherit from them guilt for their first sin, and so all but two humans are born bearing a burden of guilt. The Augustinian doctrine of original sin is morally problematic just because it attributes innate guilt to humans. It was criticized by John Locke and Immanuel Kant.

1 Actual sin

Actual or personal sins are individual human actions that are offensive to God. Since God is conceived of in the major theistic religions as morally perfect, all wrongdoing will be offensive to God and hence will be sinful. Most theists hold that some things would be morally wrong even if there were no God; only theological voluntarists suppose that nothing would be morally wrong if God did not exist (see Religion and morality §1; Voluntarism). On the majority view, much of morality is independent of the existence and will of God; divine prohibitions do not make such things as murder, torture or rape wrong. Divine commands to refrain from doing such things serve to reinforce an independent morality. Murder becomes, so to speak, doubly wrong when forbidden by God. It is a wrong against the victim and it is a wrong against God, but it would still be wrong even if, on account of the nonexistence of God, it were not sinful. Actions of this kind are such that their moral wrongness is independent of their sinfulness.

However, not all actions are of this kind. It is commonly thought that we have a moral duty to express gratitude to our benefactors. If God created us and conserves us in existence and if the gift of life is on the whole good, then we have a duty to express gratitude to God. It would be morally wrong and hence sinful not to do so. But if there is no God, we do not owe such a debt of gratitude, and so it would be neither morally wrong nor sinful not to express gratitude to God. So some actions are such that both their moral wrongness and their sinfulness depend on the existence and actions of God. For such actions moral wrongness is not independent of sinfulness.

A third possibility worth considering is that there are distinctively religious duties which are not also moral duties. It seems to be morally indifferent whether one worships God on one day rather than another, or using one ritual rather than another. But God may have prescribed the form worship is supposed to take. If so, it would be offensive to God and hence sinful not to worship in the prescribed manner. Yet it is at least arguable that it would not be immoral to fail to worship in the prescribed manner even if, because of a duty of gratitude to God, it would be morally wrong not to express reverence to God in some manner. So perhaps there are also actions or omissions that are sinful even though they are not morally wrong.

There are thus at least two varieties of actual sin. There are actions or omissions that are morally wrong whether or not God exists but are also sinful if God exists. And there are actions or omissions that are neither morally wrong

nor sinful if God does not exist but are both morally wrong and sinful if God exists. In addition, there may be actions or omissions that are neither morally wrong nor sinful if God does not exist but are sinful yet not morally wrong if God exists.

A distinction can be drawn between objective and subjective actual sin. If people do what is objectively offensive to God, they sin objectively and acquire objective guilt. If people do what they believe to be offensive to God, they sin subjectively and acquire subjective guilt. If God exists, there will be cases in which people sin both objectively and subjectively, cases in which people sin objectively but not subjectively, and cases in which people sin subjectively but not objectively. The guilt of actual sin renders the sinner liable to punishment by God if appropriate conditions on responsibility are satisfied. A person who sins both objectively and subjectively and whose true beliefs about what is offensive to God are well warranted may deserve severe punishment. A person who sins objectively but not subjectively and whose lack of true beliefs about what is offensive to God are not the result of culpable ignorance may deserve little or no punishment. In general, the relations among actual sin, guilt before God, responsibility and desert of punishment in the theistic religions are similar to and no more problematic than the relations among wrongdoing, moral guilt, responsibility and desert of sanctions in common morality. This is not the case for Augustinian original sin.

2 Augustinian original sin

The roots of the doctrine of original sin lie in the story of the Fall of Adam and Eve. When they disobey a divine command and eat the forbidden fruit, God punishes them with toil, suffering and death. Being subject to such things is part of a legacy we inherit from them. But the story does not force us to conclude that they are also to be thought of as punishments in our case. Nor does it clearly suggest that we have also inherited from the first humans a burden of guilt. That suggestion derives from the Epistles of Paul.

Seeking to appropriate the contents of the Hebrew Bible for Christianity, Paul reads it as full of foreshadowings of things that only come to fruition in the life and death of Jesus Christ. In Romans, he powerfully contrasts Adam and Christ, beginning as follows: 'Therefore, just as through one man sin entered the world and with sin death, death thus coming to all men in as much as all sinned' (5: 12). He concludes: 'Just as through one man's disobedience all became sinners, so through one man's obedience all shall become just' (5: 19). The obedience (good action) of Christ is said to be that through which all shall become just (have positive moral status); this completely contrasts with the disobedience of Adam, through which all became sinners. The implication is that everyone acquired the negative moral status of being sinners through Adam's disobedience, which would be easily explained on the assumption that guilt is somehow transferred from Adam to his progeny in a way that parallels the transfer of justice from Christ to those who benefit from his atonement.

Augustine (§§6, 9) explicitly makes this assumption. He tells us that 'when the first couple were punished by the judgment of God, the whole human race, which was to become Adam's posterity through the first woman, was present in the first man' (*De civitate Dei*, book 13: 271). All humans were present in Adam because human nature was present in Adam's semen. So we are all born in the condition of being soiled by sin, doomed to death and justly condemned (such is our nature), and this condition is part of what we would today refer to as our genetic endowment because it propagates biologically from Adam to his posterity by means of semen. As *The New-England Primer* neatly summarizes this doctrine of innate sin and guilt: 'in Adam's fall, we sinned all'. When he tries to defend it against his Pelagian opponent Julian of Eclanum, who rejects it, Augustine frequently appeals to the authority of Pauline texts such as Romans 5: 12 and 5: 19 (see Pelagianism).

Many scholars doubt the legitimacy of the appeal to Romans 5: 12. As they see it, Augustine misinterpreted that verse because he read it in Latin rather than in the original Greek. Apparently he took it to say that through one man sin entered the world and with sin death, death thus coming to all men, *in whom* all sinned; he mistakenly supposed that the final clause referred back to the one man, Adam, which led him to conclude that Adam's fall brought about not only universal death but also universal sin. But even if this conclusion is not supported by Romans 5: 12, it does seem to be supported by Romans 5: 19, and so the Augustinian doctrine of original sin appears to have a basis in scriptural texts. It was accepted by most Western Christian thinkers for more than a millennium, and it is still accepted by many Christians. It bears a striking resemblance to the archaic account of pollution that infects a person from without.

The Augustinian doctrine of original sin was elaborated in the work of medieval theologians such as Anselm of Canterbury (§8). According to Anselm, human beings are metaphysical composites that include both a nature, which makes each - like others - human, and a principle of individuation, which makes each a particular person distinct from all others. Original sin is sin that one contracts with human nature at the very origin of one's existence as a person; it is innate and unavoidable. It consists of a will that lacks a proper upright orientation because it is not subject to the will of God. Anselm describes the process by which their descendants derive original sin from Adam and Eve in terms of a principle of causal transmission. It states that 'as what is personal passes over to the nature, so what is natural passes over to the person' (*De conceptu virginali et peccato originali*: 202). By the first half of this principle, the sin Adam and Eve committed when they disobeyed God caused human nature to become sinful; by its second half, sinful human nature in turn causes their descendants to be sinful from the very first moment they possess it. And Anselm draws a shocking conclusion from the Augustinian doctrine. It is that infants who die unbaptized, before having committed any personal sins of their own and so with only the stain of original sin on their souls, are condemned by God, who is morally perfect, to exclusion from the kingdom of heaven (see Limbo §1). Many of Anselm's successors, including Thomas Aquinas, Martin Luther, John Calvin (§4) and Jonathan Edwards, played other variations on this Augustinian theme.

3 Modern philosophical critiques

Important philosophers of the modern era have been critical of the Augustinian doctrine of original sin. Locke (§1) tried to undermine its scriptural support by reinterpreting the Pauline texts cited by Augustine, and Kant (§11) proposed to substitute for it his doctrine of radical evil.

Locke's procedure is to quote a verse, then to offer his own paraphrase of it, and finally to argue in support of the paraphrase in an appended note. The paraphrase of Romans 5: 12 goes as follows:

> Wherefore to give you a state of the whole matter from the beginning. You must know, that as by the act of one man Adam the father of us all, sin enterd into the world, and death, which was the punishment annexed to the offence of eating the forbidden fruit enterd by that sin for that Adams posterity thereby became mortal.
>
> (1707: 523)

Having, in effect, substituted 'became mortal' for 'sinned' at the end of the verse, Locke has blocked both the inference that sin is inherited as well as death and the inference that death is a punishment for sin in Adam's posterity. In the note, he tries to justify this substitution by claiming that Paul is using metonymy, that is, substituting the cause for the effect, sin in Adam being the cause of his mortality and, through him, the cause of the mortality of his posterity.

Similarly, Locke's paraphrase of Romans 5: 19 is this:

> For as by one mans disobedience many were brought into a state of mortality which is the state of sinners soe by the obedience of one shall many be made righteous. i e be restord to life again as if they were not sinners.
>
> (1707: 527)

The justificatory note is terse: '*Sinners*. Here St Paul uses the same metonymie as above ver. 12 putting *sinners* for *mortal* whereby the Antithesis to righteous is the more lively' (1707: 527). We could always paraphrase away talk of Adam's disobedience making his progeny sinners in favour of talk of Adam's disobedience making his progeny mortal, thereby undercutting the scriptural basis for Augustinian original sin, if Locke's metonymy gambit were successful across the board. However, not many biblical scholars are persuaded that it is successful.

Kant flatly rejects the Augustinian doctrine of inherited sin and guilt:

> However the origin of moral evil in man is constituted, surely of all the explanations of the spread and propagation of this evil through all members and generations of our race, the most inept is that which describes it as descending to us as an *inheritance* from our first parents.
>
> (1793: 35)

Yet Kant holds that there is, in a sense, radical evil in human nature because there is in all humans, as far as we can tell, a morally evil propensity to evil. It is this propensity that is the proxy for original sin in his philosophy of

religion; he even calls it *peccatum originarium*.

A propensity, Kant tells us, is a predisposition to crave a delight which, when once experienced, arouses in the subject an inclination to it. Those who have a propensity for chocolate, for example, do not desire chocolate before they first taste it, but once they have sampled it they develop a craving for it. Kant describes propensities of this sort as physical because they belong to their possessors considered as beings determined by natural laws. Whatever is determined by natural laws is morally indifferent, and so physical propensities are morally indifferent. If all propensities were physical, then even if there were a propensity for evil in humans it would not itself be morally evil. So there must be nonphysical propensities if a propensity for evil is to make its human possessors morally evil. For Kant, nothing is morally evil but free action and what derives from it, and so a propensity for evil that is itself morally evil has to be a product of the exercise of freedom. Though the propensity for evil can, according to Kant, be represented as innate, it should not be represented merely as innate; it should also be represented as brought by humans upon themselves. It can be represented as innate in its possessors because, as the underlying ground of all morally evil actions, it is to be thought of as present in them antecedent to all such actions and so represented temporally as present in them as far back as birth. It should be represented as brought by humans upon themselves because, being morally evil, it has to be a product of freedom for which its possessors are accountable. And it can be represented as brought by humans upon themselves because it can be thought of as the product of an atemporal act of noumenal freedom.

On Kant’s view, there is radical evil in human nature only in the sense that, as far as we can tell on the basis of the available evidence, all humans have brought upon themselves a morally evil propensity for evil. This propensity is not transmitted to us causally from our remote ancestors; it is not part of the genetic endowment that comes to us through sexual procreation. When Kant endorses the formula ‘in Adam all have sinned’, he means only to say that the story of the sin of Adam and Eve represents in a symbolic fashion something that actually occurs in every human life. Whether the Kantian account of radical evil is an improvement on the Augustinian doctrine of original sin depends heavily on the plausibility of Kant’s assumption that there are atemporal acts of noumenal freedom. Many philosophers do not consider it even remotely plausible.

4 Contemporary philosophical critiques

Original sin has not been a major issue in the philosophy of religion of the twentieth century. However, some Christian philosophers have added to the criticism of the Augustinian doctrine of innate guilt.

Richard Swinburne (1989) acknowledges that humans have an innate proneness to sin. It stems from the strong selfish desires that are part of our evolutionary heritage and it is genetically transmitted. Although he describes this proneness to wrongdoing as original sinfulness, he insists that the bad desires in which it consists incline without necessitating and so do not inevitably issue in actual wrongdoing. And he emphatically rejects the doctrine of original guilt according to which all of Adam’s descendants are guilty of Adam’s original sin. He argues that one cannot be guilty in a literal sense for the sins of another unless one had some obligation to deter that person and failed to do so. Since no one alive today could have had an obligation to deter Adam and Eve, we cannot be guilty for their first sins. Swinburne also cites Scripture to support his view: ‘The son shall not bear the iniquity of the father, neither shall the father bear the iniquity of the son; the righteousness of the righteous shall be upon him, and the wickedness of the wicked shall be upon him’ (Ezekiel 18: 20). As he sees it, the guilt we acquire when we fail in our obligations to deter others from wickedness is the only literal exception to this sound prophetic claim.

The doctrine of original guilt was taught by the federal theology of the Reformation. According to federalism, Adam was, by covenant with God, the federal head or representative of the whole human race. All of Adam’s posterity stood their probation in him, and so guilt for his sin is imputed to them by God in consequence of his having fallen while acting as their covenant head. Federal theologians do not deny that Adam’s progeny were seminally present in him or that a proneness to sin is biologically transmitted from Adam to his posterity. However, they insist that guilt for Adam’s first sin extends to his descendants not by way of biological transmission but by way of divine imputation. The Puritan theologian and philosopher Jonathan Edwards (1758) defended the account of original guilt offered by the federal theology. In a critical examination of his views, William Wainwright (1988) explores various models of the moral or legal relations that might be involved in Adam being the covenant head or representative of his posterity. Some of these models permit the transfer of liability from one person to another, but none of them allows for the transfer of guilt. According to Wainwright,

the reason for this is that one must have committed an act to be guilty of it and one cannot commit another's act. His conclusion is that 'even though liability can be transferred from one person to another, guilt cannot. Adam's posterity cannot be guilty of Adam's fault unless Adam's act is somehow *literally* their own' (1988: 47). But, of course, none of the acts of any of one's ancestors is literally one's own.

Sirhak

Sirhak refers to the reformist scholarship and thought in Korea during the latter half of the Chosôn (Yi) Dynasty (1392-1910). The term was coined in the twentieth century to refer to the writings of individual scholars from the eighteenth to the mid-nineteenth centuries who were critical of the existing political, social and economic conditions.

As Korea recovered slowly from the devastations suffered from the two major foreign invasions by the Japanese (1592-8) and the Manchus (1636), the ruling Chosôn dynasty was faced with many serious political, social and economic problems, due largely to the political infighting and ineptitude of the ruling circle. At the same time, the traditional emphasis on strict adherence to neo-Confucian orthodoxy created a climate of intellectual rigidity, as the overriding philosophical concerns centred mostly on abstract and metaphysical issues such as debates on the primacy of the principle (*i*; in Chinese, *li*) and the material force (*ki*; in Chinese, *qi*), and on ritual formalities (see Confucian philosophy, Korean). It was in reaction to this that *sirhak* (practical learning) scholarship arose. Turning away from the conventional emphasis on abstract issues, the *sirhak* scholars dealt with more practical questions ranging from the classics and political economy to science and agriculture. In general, their encyclopedic writings emphasized four broad areas: the role of the government in promoting and protecting the welfare of the people, the practical use of knowledge, empirical evidence for knowledge and consciousness of Korea's identity.

Mindful of the well-being of the people, the *sirhak* scholars criticized the government and its policies for failing to protect the people adequately and proposed wide-ranging reforms of various institutions and practices. Seeing inequity in land holdings as the primary source of social ills, many proposed land reforms. Yu Hyôngwôn (1622-73) and Yi Ik (1681-1763) made proposals that would assure that farmers had their land to cultivate, while Chông Yagyong (1762-1836) called for a 'village land system' whereby villagers would jointly own the land and work together, sharing the harvest in proportion to the amount of labor each put in. Along with Yu Suwôn (1694-1755) and other *sirhak* scholars, they severely criticized the rigid social structure that granted privileges to the elite *yangban* social class based on birth. The abusive practices of the civil service examination system were also blamed for contributing to the social ills of the time. Through his satirical novellas, which resemble those of Voltaire, Pak Chiwôn (1737-1805) condemned the hypocritical life led by the *yangban*. Envisaging a more egalitarian society, the *sirhak* scholars wanted to do away with privileges based on birth and to make government more responsive to the needs of the people (see Equality).

The *sirhak* scholars believed in the practical application of knowledge in daily life. Agriculture was of special interest to many *sirhak* scholars, and Pak Sedang (1629-1703), Hong Mansôn (1643-1715), Sô Hosu (1736-99) and Sô Yugu (1764-1845) wrote extensively on soil conditions, fertilizer, irrigation, horticulture, sericulture, livestock, forestry and similar subjects in order to improve the condition of the peasants. Unlike the conventional Confucian scholar-officials, many *sirhak* scholars recognized the importance of trade and commerce. For Pak Chega (1750-1805), prudent consumption was necessary to create demand for production; he wanted the government to encourage domestic as well as international trade. The introduction of Western science and technology also stimulated the thinking of many *sirhak* scholars. Kim Sôngmun (1658-1735) and Hong Taeyong (1731-83) wrote extensively on mathematics and explained terrestrial movement within a solar system. Based on knowledge acquired from China, Chông Yag-yong devised cranes that were used to construct the new city of Suwôn and developed inoculations for measles and smallpox.

There was also a growing interest in historical and geographical studies of Korea. An Chôngbok (1712-91) rewrote Korean history, emphasizing the legitimacy of the Korean rulers starting from Tangun. In his monumental study of Korean history, Yi Kûngik (1736-1806) tried to present an objective history unhampered by factional biases. Yu Tûkkong (1748-1807) was the first historian to treat the kingdom of Parhae (Po-hai in Chinese) (699-926) as an integral part of Korean history. In historical geography, Sin Kyôngjun (1712-81), Han Chinsô (1777-?) and Chông Yagyong traced Korea's boundaries at various historical periods, while Yi Chunghwan (1690-1752) presented an authoritative study on the cultural and economic characteristics of various regions of Korea. Kim Chôngho (*fl.* 1834) produced several maps of Korea that are remarkably detailed and accurate even by modern standards. These studies enhanced consciousness of Korea's own identity.

Many *sirhak* scholars emphasized that knowledge is founded on empirical evidence. In his studies of the classics, Chông Yagyong wanted to go back to the texts of Han times or earlier for verification, in the belief that the classical canons are not necessarily the final words we must accept in faith, but merely the records of the ancient sages in search of betterment. Perhaps the most articulate proponent of empiricism in Korea was Ch'oe Hangi (1803-79). Upholding the primacy of *ki* (material force) over *i* (principle), Ch'oe emphasized that knowledge is acquired through the perceptions of our senses and that even the Mencian notion of humanity, righteousness, propriety and wisdom is derived from our experience, not from innate knowledge (see Mencius). Ch'oe Hangi is often regarded as an intermediary between tradition and modernity in Korea.

As the proposals of the *sirhak* scholars contained certain elements of the modernistic ideas, many Korean scholars tried to characterize them as the forerunners of modern Korea. However, the *sirhak* scholars envisioned their reform ideas within the bounds of the Confucian worldview, and regarded themselves as the heirs of the Confucian tradition.

Situation ethics

'Situation ethics' accords morally decisive weight to particular circumstances in judging whether an action is right or wrong. Thus we should examine critically all traditional rules prohibiting kinds of actions. Proponents of these views have exerted their greatest influence in Europe and North America in the twentieth century, although such influence waned by 1980. The views received extensive scrutiny in Christian communities. Three quite different warrants were offered for privileging discrete situations. First, we should remain dispositionally open to God's immediate command in a particular time and place (theological contextualism). Second, we should take the actual consequences of particular actions as morally decisive (empirical situationism). Third, we should be ready to perform actions that compromise moral ideals when doing so improves matters in ways a given situation, with its distinctive constraints, makes viable (mournful realism).

St Augustine's famous dictum, 'Love, and do what you will', summarizes the views that many proponents of situation ethics commend. Doubtless it would distress Augustine to see his dictum employed to support views he himself repudiates. He holds that a motive of love is a necessary condition for a good action, yet denies that it is a sufficient condition. Indeed, he claims that certain actions are wrong in themselves. Those forbidden absolutely include murder, lying, and adultery (see Deontological ethics).

Proponents of situation ethics, for their part, adopt his dictum, but reject his stipulation that there are certain things that are always wrong. They attend instead to the distinctive features of the case at hand. Situation ethics is thus a movement that protests generally against the imposition of unchanging moral absolutes that prohibit everywhere certain classes of conduct. Yet deeper currents contributed to the widespread debates the movement occasioned earlier in the twentieth century (roughly until 1980), both in Europe and North America. Some currents came from secular communities, where existentialist thinkers stressed the importance of 'authentic' personal decisions, and attacked rules that blocked spontaneity and awareness of change (see Existentialist ethics). Other currents came from Christian communities, where so many of the debates occurred, and where three warrants for concentrating on particular situations proved especially influential.

One warrant - theological contextualism - stems from the claims that Søren Kierkegaard advances in *Frygt og Baeven* (*Fear and Trembling*) (1843). He examines the biblical narrative of Abraham's near-sacrifice of Isaac. Kierkegaard insists that Abraham cannot 'love' Isaac if he disobeys God's command, and that Abraham paradigmatically displays a dispositional openness to God's immediate command. We can suppose for the best of human reasons that a given action is wrong, but if God commanded it in a certain context, we should have to change our minds. Twentieth century religious thinkers who extend a case for immediacy include Karl Barth and Emil Brunner. The particular situation has priority over 'code morality' in that it must be *God* who commands in the present moment. We may jeopardise divine sovereignty and be diverted from a personal confrontation with God by claiming to know in advance what we should do and forbear so that we only interpret, apply, and execute this knowledge. The enterprise of 'casuistry' with its subsumption of cases is thought, fairly or not, to afford an opportunity for such diversion (see Casuistry). Commended in its place is a kind of act-deontology. God's immediate command, self-interpreting in a particular situation, may sometimes lead us to suspend our antecedent moral judgments.

A second warrant - empirical situationism - jettisons any appeal to immediate divine commands, and proceeds instead to apply directly to each situation the general injunction 'to love your neighbour as yourself'. In *Situation Ethics* (1966), Joseph Fletcher contends that we should determine what action is right in a particular situation by confronting our loving wills with the contextual details of the situation itself. He allies his 'situationism' formally with modified act-utilitarianism (see Utilitarianism). Neighbour-love, like utility, is the sole governing criterion that should always guide action. Other subsidiary precepts and rules, including the traditional prohibitions that Augustine takes as absolutes, Fletcher affirms only as 'illuminative maxims'. They are at most 'statistically preponderant generalizations', based on past cases and cumulative experience that inform us of the kinds of action that typically produce good or bad consequences. But we should suspend or reject maxims whenever it seems more loving to do so, that is, whenever we effect more good by breaking them than by adhering to them. If a traditional maxim proves unloving in this situation, we should disregard it, without remorse, and without a sense of

conflicting obligations.

A final warrant - mournful realism - accents the moral compromises a particular situation may exact. In *The Nature and Destiny of Man* (1949), Reinhold Niebuhr laments that a particular situation may present us with unwanted choices, and induce us to consider doing things we may judge repellent, or at least things we would never do for their own sake. But he justifies making choices we do not want to make, when the alternative is to acquiesce to corrupt forces that threaten altogether the conditions for a tolerable community.

This third warrant is like the second in several ways. It judges that immediate divine commands are not possibilities to be taken routinely into account. Neighbour-love remains insuperable. No one subsidiary precept or rule binds absolutely, whatever the consequences. Contextual details may assume effective priority in determining what actions are appropriate. There are, however, some differences. Fletcher is too complacent when he maintains that the greatest moral good possible in a situation is the most loving thing to do. For what is possible often demands compromise that leaves us morally dissatisfied. Compromise never becomes *all right*. Fletcher also goes wrong in weighing all considerations from the ground up each time we decide. While subsidiary precepts and rules are not exceptionless or always decisive, they should never be omitted from consideration in any situation in which they are relevant. Some carry a presumption in their favour. They are not to be disregarded but only overridden, with compunction, and with a sense of competing obligations.

Although situation ethics as a self-conscious movement with its own internal debates faded, the importance of the issues it addressed persists. It still has lessons to teach.

Skinner, Burrhus Frederick (1904-90)

B.F. Skinner advocated a philosophy of psychology, called 'radical behaviourism', as well as a substantive psychological theory, 'scientific behaviourism'. Radical behaviourism restricted psychology to establishing lawful links between the environment and behaviour, rejecting the 'mind' as a 'needless way station' mediating the two. Scientific behaviourism proposed specific links, the laws of 'operant conditioning', whereby behaviours are 'reinforced' by the consequences they have had in an animal's past. Although Skinner brought to psychology new standards of experimental rigour, and managed to train animals to do remarkable things, there are serious limits to the range of behaviours scientific behaviourism can explain. Both it and radical behaviourism have been obviated by the development of a computational theory of mind.

Influenced by reading Bertrand Russell, Skinner become an adherent of Watson's thesis that 'everything that can be known about man is discoverable by the method of external observation' (1925), that is, that none of our knowledge depends upon introspection; a doctrine called 'methodological behaviourism'. Skinner went further and concluded from this that any serious psychology should therefore confine itself to finding lawful relations between externally observable stimuli and responses, rejecting internal mental states as 'needless way stations' (1963), a doctrine called 'radical behaviourism' (see Behaviourism, methodological and scientific). Skinner often identified mentalism with dualism, which he thought entailed that the mental was essentially 'private'. Alternatively, he sometimes endorsed a version of 'analytical' behaviourism, according to which the meaning of mental talk is be *analysed* in terms of (dispositions to) overt, publicly observable behaviour. Sometimes he even seemed to abandon behaviourism for mere physicalism, allowing psychology to refer to mental events so long as such terms as 'being hungry' or 'thinking to oneself' were physical events in the brain.

Skinner made two very important contributions to the more substantive theory, scientific behaviourism. First, he broadened Pavlov's work (1927) on 'classical conditioning' to include not only elicited, but spontaneous behaviours (what he called 'operants', since they operated in the environment), subsuming them all under Thorndike's 'law of effect' (1911). This says, roughly, that the probability of a response *R*, given a stimulus *S*, is increased/decreased if *R* following *S* has been paired with a positive/negative reinforcement *F* (for example, a reward or a punishment) in the past. Thus, for example, if a baby says 'Ma' [*R*] in front of its mother [*S*], and the mother hugs the child [*F*], the probability of the child saying 'Ma' in front of the mother again increases. Skinner believed that by suitable patterns of conditioning one could explain all the intelligent behaviour of people and animals, which, moreover, could be 'shaped' into almost any form. He wrote popular works expounding this view, most notably his utopian novel, Walden Two, and a philosophical tract, Beyond Freedom and Dignity, in which he draws the kinds of consequences for the ordinary conception of freedom that are drawn by many other determinists (see Free will).

Second, Skinner brought to light surprising facts about the patterns (or 'schedules') of reinforcement, for example, that they were more effective when they were intermittent, rather than constant, and that punishments were often ineffective in delicately shaping behaviour (see Ferster and Skinner 1957; Skinner 1969). These findings remain interesting even for those who reject behaviourism.

Problems with scientific behaviourism arose primarily in explaining the very behaviour of rats in mazes that was supposed to be the theory's parade example. Rats can learn 'latently' (without reinforcement, when they have been sated) or 'passively' (without emitting responses, as when they are wheeled through a maze in a wagon), and can improvise new, appropriate behaviour that has not been reinforced (for example, rats trained to run a maze will swim it when it is flooded). Both this and other ethological evidence suggests that animals in general navigate not by associating stimuli with responses, but by exploiting some sort of internal 'map' (Tolman 1948), and/or computation on vectors that indicate how long they have moved in a certain direction (Gallistel 1990).

One of Skinner's reasons for spurning the mental had to do with a philosophically motivated rejection of 'intervening variables' in an explanation. His complaint here was not that the mind did not *exist*, but that it was *irrelevant* to scientific explanation.

> We cannot account for the behaviour of any system while staying wholly inside it; eventually we must turn to forces operating on the organism from without. Unless there is a weak spot in our causal chain so that the

> second link is not lawfully determined by the first, or the third by the second, then the first and third links must be lawfully related.
>
> (1953: 35)

Hempel (1965) discussed this issue generally as 'the theoretician's dilemma' (see Explanation).

The argument assumes that in the usual case there is a three-term causal relation consisting of some set *E* of environmental events causing some set *P* of psychological/neural events, which in turn cause some set *R* of behavioural responses. The transitivity of 'cause' suggests that the middle link can be dropped. However, this begs several questions. It assumes that explanation is concerned only with predicting observable phenomena, for example, that it is only *R* that needs explaining. But what if we want to know what explains *P*, for example, why some organism is thinking to itself or wants to eat? Surely *P* cannot be dropped in that case.

More crucially, there is the further important assumption, inherited from classical empiricism, that most interesting causal chains start in the environment. However, some behaviour may result in part from endogenous features of an individual's neurochemistry or from maturational patterns determined by biological evolution. Some species of bird are disposed to learn about the positions of stars *only* when they are young and unable to fly, and become *unable* to learn about them when mature (Emlen 1969). One of Skinner's most penetrating critics, Chomsky (1959), argued that the remarkable rapidity with which children learn their first language requires that substantial knowledge of 'universal grammar' be innate (see Chomsky, N.; Language, innateness of).

Scientific behaviourism brought to psychology a higher standard of experimental rigour than it had previously enjoyed, and led to more disciplined tests for even non-behaviourist claims. However, apart from his findings about schedules of reinforcement, few of Skinner's claims remain influential. Scientific behaviourism has been eclipsed by the rise of cognitive and computational theories in psychology that, moreover, obviate the strictures of radical behaviourism, since these theories are compatible with materialism, and are entirely open to public verification.

Skovoroda, Hryhorii Savych (1722-94)

Skovoroda was the first truly independent philosopher produced by Ukraine and the last brilliant exponent of its Baroque culture. Departing from the Aristotelian tradition of the Kiev Academy, he constructed an original synthesis of ancient and patristic thought. Because of his classical aloofness from history, the sociopolitical trauma of Ukraine's absorption by Russia, which he witnessed, is hardly reflected in his writings. His worldview foreshadows the Romantic and religious tendencies in nineteenth-century Ukrainian and Russian thought.

Hryhorii Skovoroda (born in Chornukhy, died in Pan-Ivanivka, Ukraine) interrupted his studies at the Kiev Academy first in 1741-4 to sing in the court choir in St Petersburg and then in 1745-50 to serve as music director at the Russian imperial mission in Tokai, Hungary. Returning to Ukraine, he taught poetics at Pereiaslav College and then resumed his studies in Kiev (1751-3). After serving as private tutor, he taught poetics (1759-60), syntax and Greek (1762-4) and Christian ethics (1768-9) at Kharkiv College. Dismissed because of his unorthodox teachings, he spent the rest of his life wandering from friend to friend and writing. Most of his works belong to this period: over a dozen verses, thirty fables, two treatises, twelve dialogues and over 100 letters. His manuscripts were copied and circulated among his friends; none was published during his lifetime.

Skovoroda's style of writing is largely responsible for the widely differing interpretations of his thought. He conveyed his ideas mostly through imagery, similes, metaphors, fables, myths, parables and proverbs. Even philosophical terms are often defined by images, leading to ambiguity in his doctrines. Little clarity can be gained by seeking logical links among his doctrines: he did not arrange them into a system and rarely made explicit logical connections. His favourite devices of persuasion are analogies and illustrations, not arguments. Often, he ignores the implications of his teachings - the obvious questions and difficulties that follow from his statements. Thus, some scholars have viewed Skovoroda as an eclectic without a coherent body of doctrine. Most, however, agree that there is an inner unity to his thought. But then they differ on how his ideas fit together: some take his metaphysical teachings to be central and treat him as a theologian or mystic, others claim that he is a moral thinker. There are also diverse interpretations of his principal doctrines such as God's relation to the world, personal immortality and the nature of matter.

The purpose of philosophy for Skovoroda is practical - to show the way to happiness; hence the key questions are 'What is happiness?' and 'How can it be attained?'. He defines happiness as an inner state of joy, peace and confidence. To reach this state one must know some basic truths about oneself and the world. Skovoroda limits his metaphysical and anthropological teachings to those he regards as necessary for happiness. He shows no interest in theoretical questions that have no immediate bearing on existence.

Skovoroda divides reality into three worlds: the macrocosm or universe and two microcosms - man and the Bible. All three have a similar dualistic structure: they consist of an inner ideal nature that is spiritual, eternal and immutable and an outer sensible nature that is material, transitory and changing. The inner nature is higher; it imparts being to the outer as a tree supports its shadow. In the macrocosm, the inner nature is God and the outer is the physical universe. This position is panentheist, rather than pantheist, for God is in things through his ideas, not immediately. Although parts of the universe are transitory, the universe as a whole shares in God's eternity; hence matter is eternal.

In man, the inner nature is the spirit, soul, heart or true man; the outer is the body. It is unclear whether Skovoroda takes the true man to be a universal being common to all human beings or something unique in each individual. In any case, the soul can know itself more easily than it can know other souls; thus, all knowledge of spiritual reality begins with self-knowledge.

The symbolic microcosm or Bible consists of images of all the things in the macrocosm. The Bible's inner nature is the symbolic meaning, the higher truth known by the wise men of all ages; its outer nature is the literal meaning, which is often mistaken for truth itself. The purpose of biblical stories is to lead the reader to higher knowledge; the people and events described in the stories are insignificant and the miracles, which are contrary to nature, are fictional. Skovoroda interprets biblical symbols so as to show that the Bible's true meaning is expressed in his philosophy.

From this metaphysical scheme Skovoroda draws a number of practical conclusions. Since what is most valuable in us is eternal, we have no reason to fear death. Nor have we any reason to fear privation in this life, for Providence guarantees the necessities of happiness for all. The principle that what is necessary (for happiness) is easy and what is difficult is unnecessary serves as a criterion of rational need and reasonable expectation. Besides absence of fear, happiness requires self-fulfilment - the active pursuit of one's God-given innate calling or congenial task (*srodnoe delo*). To work in one's vocation, regardless of hardships, is to be happy, while to assume an unnatural task is to suffer hellish torment regardless of external rewards. Furthermore, since vocations are distributed by God in such a way as to ensure social harmony, to evade one's vocation is to introduce disorder into society and to harm others. The doctrine of congenial work is central to Skovoroda's moral system and the foundation of his optimistic attitude to life.

Skovoroda's influence on Ukrainian or Russian philosophy was negligible. His poetry was popular among the common people and valued by the founders of Ukrainian vernacular literature in the nineteenth century. During periods of cultural revival in the twentieth century, Ukrainian writers found inspiration in Skovoroda's ideas and independent personality.

Slavery

The moral, economic and political value of slavery has been hotly disputed by philosophers from ancient times. It was defended as an institution by Plato and Aristotle, but became increasingly subject to attack in the modern period, until its general abolition in the Western world in the nineteenth century.

In the twentieth century our belief that slavery is fundamentally unjust has become a benchmark against which moral and political philosophies may be tested. Both utilitarians and contractarian philosophers have argued against slavery in general and the enforceability of slavery contracts more specifically, although for very different moral reasons. Others have argued that only by viewing slavery from the standpoint of the slave can its moral significance be understood.

1 Classical views of slavery

Slavery was widely practised in the ancient world, in different forms. In the Old Testament, the practice was generally limited to the women and children of the enemies of the Israelites, and was said to be instituted by God (Genesis 9: 25). The men of defeated cities were all killed (Deuteronomy 20: 13) as, often, were the women and children (2: 34, 3: 6). But women and children could be spared and enslaved by the conquerors (2: 14). Slavery also appears to be sanctioned in the New Testament, where slaves are told to obey their masters (Ephesians 6: 5; Colossians 3: 22; Titus 2: 9).

The Greeks, in contrast, often acquired adult male slaves by military means, and even conceived war as a form of hunting for slaves (Aristotle, *Politics* I.7.1255b37-40). There has been some debate over whether Plato envisaged the ideal state he describes in *Republic* as including the practice of slavery (see Wild 1953 versus Vlastos 1968), but the reference to slaves at *Republic* 433e would appear to leave no doubt in the matter. Certainly, they were included in the state described in Plato’s *Laws* (for example, 773e).

Plato never offers a whole theory of slavery, but it is clear from what he does say that the true slave is one who lacks reason (*Laws* 966b). This Platonic conception of the slave may also be found in what is certainly the most extensive philosophical treatment of slavery in antiquity: Book I of Aristotle’s *Politics*. Aristotle seeks to defend the practice of slavery as a just social institution, on the ground that it is not merely supported by existing laws and conventions, but also by nature itself. Aristotle forms his argument as a direct reply to those who argued that slavery is unnatural (*Politics* I.6). On the contrary, Aristotle is convinced that there do exist natural slaves, who are ‘from birth marked out by nature as slaves’ (I.5.1254a21-4). Like Plato, Aristotle locates the naturalness of slavery in the natural slave’s rational deficiency: the slave, Aristotle says, wholly lacks the deliberative part of the soul (I.13.1260a12), and may even be conceived as no more than a part of the natural master’s body (I.6.1255b11-12). Natural slave and natural master are both benefited by the institution of slavery: the master through access to the labour of the slave, the slave through access to the deliberative ability of the master. Aristotle concedes that purely conventional slavery - where those naturally suited to be masters are enslaved, or those naturally suited to be slaves become masters - is morally indefensible.

Both Plato and Aristotle are highly critical of what they regarded as the excessively lenient treatment slaves received in democracies (*Republic* 563b; *Politics* VI.4.1319b28). Modern thinkers may well wonder at such an assessment in the context of democratic Athens, in which slaves were treated - by modern lights - very harshly indeed: slaves could be beaten at the whims of their owners (MacDowell 1978). But Aristotle also thinks that Plato’s conception is excessively harsh, for Plato imagines that even the use of admonition ‘spoils’ the slave (*Laws* 773e), whereas Aristotle argues that the slave is even more appropriately admonished (as opposed to simply commanded) than is a child (*Politics* I.13.1260b5-7). It is problematical what Aristotle may have thought merited the rationalizations of admonition in the slave given that Aristotle makes his case for the naturalness of slavery precisely on the ground that the slave lacks reason (Smith 1991).

2 Later views of slavery

Later views of slavery through the Middle Ages combined this Aristotelian naturalism with the Christian concept of original sin. Augustine placed special emphasis on the latter; for him the ‘prime cause’ of slavery was sin, not nature (*City of God* XIX, 15). Aquinas leaned in the other direction (*Summa theologaie* Ia.96.4). Could slavery

have existed in man's natural state? By likening slavery to old age, Aquinas barely managed to avoid an affirmative answer. Slavery is occasioned by sin, but like old age and death it derives its naturalness from the rational order of being (3.suppl.52.1).

Jean Bodin dissented from early modern apologies for slavery, attacking Aristotelian and Augustinian views on empirical grounds (1606: I.5). Thomas Hobbes, who shared Bodin's preference for absolute sovereignty, took a more hypothetical view. Despite his vociferous attacks on Aristotle and 'the Schoolmen', his own argument that slavery is irrational rests, in part, on the acknowledgement that some people are better at rational deliberation than others. The problem with Aristotle's view is that lacking absolute sovereign power, this particular difference may be less salient than it seems in a more stable society. Hence, Hobbes' 'ninth law of nature' urges individuals in the 'state of nature' not to be proud and to acknowledge one another as natural equals (1651: ch. 15). For less-able deliberators the alternatives to consenting to an absolute sovereign (living as outlaws or being slaves) are worse (Kidder 1983: 142).

Despite Locke's standing as a theorist of individual liberty and his denunciation of slavery as 'so vile and miserable an estate', (1690: I.i), he gave a qualified defence of slavery as part of his conception of a just war. When an unjust aggressor wages war, the just conqueror may enslave the former (II.xxiii.85). But even where an unjust act of aggression occurs, further conditions still must be met. The conqueror cannot enslave his own conquering forces, cannot take more than is needed to repair the damages incurred in waging war, and cannot enslave noncombatants. This last qualification extends to future generations and rules out the confiscation of land because land belongs to future generations by virtue of their inheritance rights (Farr 1986: 272-3) (see Locke, J. §10).

Enlightenment philosophers, while not unanimous in their condemnation of slavery, shifted the balance of arguments more in that direction. Montesquieu, sometimes ironically, rejected Aristotle's view but added that in warm climates the threat of slavery may be needed to overcome laziness (1748: 15.7). Unsatisfied with this argument, however, he then wondered whether the laws in such climates are responsible for human laziness, and whether perhaps slavery would not be needed if there were better laws to make people less lazy (15.8). Rousseau made a similar point more forcefully. Human nature can be servile when it is enslaved, but Aristotle 'mistook the effect for the cause' (Rousseau 1762: I.ii). Neither nature nor conquest justifies slavery.

The moral stance taken by the *philosophes* against slavery gave way in the nineteenth century to a complex array of historical interpretations. Hegel argued that in the dialectical struggle for recognition the master's drive for autonomy breeds dependency upon the slave at the same time as the slave's own labour provides him with a mind of his own (Hegel 1807). Slavery, on this interpretation, is a necessary stage in the history of human emancipation. African slavery is especially necessary and should be eliminated only gradually given the African's stage of moral development (1822-30: 183).

Hegel's emphasis on the transformative power of labour captured Marx's imagination. He saw the wage worker under capitalism as engaged in something akin to the dialectical struggle for recognition between master and slave. As the 'wage-slave' shapes the product of his labour he contributes to the creation of a more self-conscious working class ([1844] 1978: 112) (see Alienation; Marx. K. §4). In contrast, Nietzsche (§8) argued that the new morality of the slave was not a form of greater, emancipatory self-consciousness, but *ressentiment* and a base preoccupation with mere existence (1887: I.10). Eventually, however, these 'last men' and their democratic societies would give way to a more noble life (1886: §202).

John Stuart Mill, against the background of a harmonious philosophy of history, focused more narrowly on the morality of voluntary slavery contracts (1859: ch. 5). Despite his strong stance against paternalism, Mill thought that slavery contracts should not be enforced for two reasons: slavery is always more harmful than freedom and freely choosing not to be free is incoherent. Scholars have questioned both arguments; under certain difficult circumstances, it is neither unreasonable nor most harmful for individuals to agree to be the slaves of benevolent slave-holders (Callahan 1985: 225).

More orthodox utilitarians since Mill have been troubled by the argument that under some conceivable circumstances they would have to permit even non-voluntary slavery. In response they claim that utilitarianism is a morality for the world as it actually is and one that respects all individuals equally (see Utilitarianism). Under

actual circumstances utilitarian moral reasoning would not justify slavery (Hare 1979). In contrast, contractualists have argued that the problem is not what could conceivably be justified on utilitarian grounds, but the administrative kind of reasons utilitarians give in actual cases. According to contractualists, slavery is wrong because the slave-holders have no moral standing and the practice of slavery would not be accepted by the slaves themselves as a reasonable, permanent form of social cooperation (Rawls 1971a: 260-6), even if in dire circumstances it was temporarily acceptable to them (Rawls 1971b: 248) (see Contractarianism §7-8).

Finally, some philosophers have argued that in addition to the question of justification, one can look back through the experience of slavery from the standpoint of the slaves, not the slave-holders, to understand more fully complex moral concepts such as paternalism, forgiveness, citizenship and resistance (McGary and Lawson 1992).

Slavophilism

In the Slav countries outside Russia the term 'Slavophilism' is a generic name for all advocates of the 'Slav idea', irrespective of their philosophical views and political commitments. In Russia, however, this term is used, as a rule, to denote one specific ideology, elaborated in the 1840s by the former members of the Schellingian circle of 'Lovers of Wisdom': Ivan Kireevskii (1806-56) and Aleksei Khomiakov (1804-60). Among its other followers, the most creative were the former Hegelians - Konstantin Aksakov (1817-60) and Iurii Samarin (1819-76). Despite some individual differences, all these thinkers shared a coherent view of the world which was expressed in their philosophical, theological and historical ideas. Their importance was not immediately recognized, but after Dostoevskii and Solov'ëv it became clear that they were the most important part of Russia's 'philosophical awakening' in the first half of the nineteenth century.

The words 'Slavophiles' and 'Slavophilism' were originally intended as gibes. The same was true of the words 'Westernizers' and 'Westernism'. All these terms, however, could be interpreted positively and were finally accepted by both sides of the 'Slavophile-Westernizer' controversy. But in the case of the Slavophiles it was a very reluctant acceptance: they felt that the term 'Slavophilism' failed to express the essential nature of their philosophical and religious position. In addition, this term contained a rather misleading suggestion as to their solidarity with non-Russian Slavs: in fact they focused their attention on the 'truly Christian' and 'purely Slav' spiritual heritage of pre-Petrine Russia. An interest in the fates of non-Russian Slavs began to play a role in their ideology only at the time of the Crimean War. This shift of focus transformed the original Slavophilism into a form of imperial Russian Pan-Slavism.

1 Theory of integral knowledge and integral personality

The first sketch of the Slavophile worldview was Kireevskii's unpublished article 'A Reply to Khomiakov' (1839). The most elaborate presentation of its philosophical foundations is Kireevskii's essay 'On the Necessity and Possibility of New Principles in Philosophy', published posthumously in 1856.

Kireevskii's philosophical views revolve around the concept of 'integral knowledge' and 'integral personality', opposed to the disintegrating rationalism and individualism of the West. In the theory of knowledge he accused rationalism of taking an anti-ontological position, separating the knower from the known and thus transforming reality into a scattering of isolated fragments, united only by a cobweb of abstract relations. The power of reason, he claimed, is purely formal and, therefore, cannot attain the 'substantive' penetration of reality; the substantial can be grasped only by substantiality, that is to say, by personality as an integral whole. True knowledge is a result of the harmonious cooperation of all the powers of the personality; the precondition of such knowledge is wholeness of spirit and a living, direct bond between the knower and reality. Hence it must be a kind of revelation, an immediate understanding available through faith. But authentic faith (and therefore knowledge) cannot be experienced by an isolated individual; it must be rooted in the supraindividual, corporate consciousness of community. This supraindividual, communal consciousness had been destroyed in the socially atomized West; it was preserved, however, by the Orthodox Church. In Kireevskii's view, membership of the Orthodox Church made it possible for the Russian thinkers to create an entirely new, truly Christian philosophy, breaking with the legacy of rationalism and providing an effective remedy for the European spiritual crisis.

In his philosophy of man Kireevskii developed the concept of 'integral personality', setting it against the Western concept of the 'autonomous individual'. He described autonomy as a divisive, destructive principle: the autonomy of the individual brings about the atomization of society, the autonomy of reason destroys the harmony of the soul, splitting human personality into separate forces, each of them claiming autonomy for itself. In this way human life becomes fragmented into different aspirations: knowledge, politics and economic activity separate themselves from religion and morality, the state separates itself from the Church, aesthetic values become divorced from moral values, and so forth. Thus the striving for autonomy is incompatible with personal wholeness. The latter can be achieved only through the bringing together of all spiritual forces, through the religious concentration of spirit.

Kireevskii presented his philosophy of 'integralism' as rooted in the Russian Orthodox tradition and derived ultimately from the teaching of the Holy Fathers of Eastern Christianity. There was some truth in this claim: it is easy to see an affinity between Slavophile antirationalism and the programmatic anti-intellectualism of Eastern

apophatic theology. Nevertheless it is fair to say that the direct source of Kireevskii's philosophy should be seen rather in the ideas of the German conservative Romantics. At the same time it must be stressed that the main target of Kireevskii's critique of rationalism was not the abstract rationalism of the Enlightenment (as was the case with the early Romantics) but the dialectical, historicized rationalism of Hegel. In a sense, Slavophile philosophy was a Russian response to the crisis of Hegelian 'Absolute Idealism'. Kireevskii, along with Khomiakov, saw Hegel as the greatest and most consistent rationalist philosopher, in whom Western thought attained its culminating point; hence the crisis of Hegelianism was for them the crisis of Western philosophy as such. They sympathized with the aged Schelling whose 'philosophy of revelation' was consciously opposed to Hegelian panlogism. They were convinced, however, that a genuinely new and truly Christian philosophy could spring only from the Russian soil (see Hegelianism, Russian §4; Schellingianism).

According to the Slavophile philosophers, Hegelian Absolute Idealism was proof that rationalism provides only an abstract, purely formal, empty knowledge, and attempts to create 'a world without a substratum'. Consequently, their own philosophical standpoint was a consistent ontologism: that is, the view that knowledge is a part and function of an existential penetration of reality. This standpoint was almost universally accepted by Russian religious philosophers of the early twentieth century. Some of them (Berdiaev, N.A. and Ern) saw in it a distinctive feature of Russian philosophy.

2 Philosophy of history

The best-known part of Slavophile ideology was their philosophy of history. It revolved around two interconnected antitheses: (1) between the 'ancient' (pre-Petrine) and the 'modern' (post Petrine) Russia, and (2) between Russia and Europe.

According to Kireevskii, Western civilization was composed of three constitutive elements: (1) Christianity, (2) the young barbaric peoples which destroyed the Roman Empire, and (3) the heritage of the ancient pagan world. The main difference between Russia and Western Europe lay in the fact that Russia lacked this ancient Roman heritage. In his pre-Slavophile period Kireevskii saw this difference as a great misfortune for his country; by the end of the 1830s, however, he came to see it as a blessing. Following some conservative German Romantics (especially Franz von Baader and Adam Müller) he saw the essence of Roman civilization in its rationalism, as embodied in the rational and formalized system of Roman law (see Romanticism, German). Due to this, the ancient Roman society was an aggregate of rationally thinking individuals, motivated solely by individual profit; the only social tie was a bond of interest; the only unity, the unity of a party. There was no real community, but only an association of isolated human beings, lacking any common faith, convictions and customs. In such a situation the only regulator of human relations was legal convention backed by the external force of the state machine.

Kireevskii believed that the juridical rationalism of ancient Rome had exerted a fatal influence upon Western Christianity and, consequently, upon the entire course of Western history. He developed this view with the aid of Khomiakov, the Slavophile theologian and historian of the Church. Rationalism, inherited from ancient Rome, was, they argued, the prime disintegrating factor in the history of Western Christianity. The Roman Catholic Church broke away from the real 'catholicity' of tradition by arbitrary changes of dogma and attempts to prove them in a rational, scholastic way. The Church became a hierarchically organized juridical institution, external and alien to her body of believers. The religious individualism of the Reformation was a justified protest against Catholic authoritarianism; its consequence, however, was atheism and the apotheosis of egoism, which laid the spiritual foundation for the modern, rational and industrial European civilization. Thus, the ancient Roman heritage, the increasing rationalism of the Western Churches, the secularizing effect of the Enlightenment, the French Revolution and, finally, modern industrialism were seen by the Slavophiles as links in one historical process, replacing organic communal ties by legal conventions and paving the way for a completely soulless, mechanical civilization.

Old, pre-Petrine Russia represented an entirely different form of social development. Russian Orthodoxy, not infected by Western rationalism, preserved the teachings of Christ in all their purity. In contrast to the West, whose political systems were formed, as a rule, as a result of conquest, the old Russian state was created by a voluntary act of the people; thus in Russia the relationship between the rulers and the ruled could be based upon mutual confidence and solidarity. The basic cell of the old-Russian social structure was the *mir*, or *obshchina* - a self-governing unit based upon communal ownership of the land, respecting old traditions and managing its affairs

according to the principle of unanimity. These elementary cells were united into larger structures ruled by the same basic principles. All ’Holy Russia’ was one great *mir*, one great community of land, customs and faith. Thus, unlike the West, it was a society where the integrating factors were not mere interests but moral convictions, not things but values.

Konstantin Aksakov, the most original thinker among the younger Slavophiles, developed these views in the direction of an extreme communitarianism, combining a kind of Christian anarchism with an apologia for autocracy. For him the contrast between pre-Petrine Russia and the West was a contrast between internal and external truth. By ’internal truth’ he meant the voice of conscience and a living tradition freely expressed in community life; by ’external truth’ he meant juridical and political forms. In his view law and state represented the sphere of society’s self-alienation; they demanded obedience irrespective of moral convictions, under the threat of physical coercion, and were therefore incompatible with morality, which they tried to replace with mere legality. The worst form of government was the modern republic since it demanded from the people an active political participation, that is an active involvement with ’external truth’.

In contrast to the West, pre-Petrine Russia accepted law and the state merely as a sad necessity, never as a principle. Autocracy in the sphere of politics was not only compatible with freedom but even an essential condition of it: it was so because true freedom is not political freedom but freedom from politics, and such a freedom could exist only under an autocratic ruler who could carry the burden of politics on his own shoulders. In Muscovite Russia the relations between the state and the land consisted in mutual non-interference: the people never tried to rule and the monarchs (with the regrettable exception of Ivan the Terrible) did not interfere with the communal life of the land. The idea of the absolute state, the state which can arbitrarily change or destroy the living principles of society, was introduced into Russia by Peter the Great. After his violent Westernizing reforms the educated classes, the ’servants of the state’, betrayed their national heritage and only the plain folk preserved in its life the old ’internal truth’. This diagnosis substantiated Aksakov’s view that the peasant commune, integrated by moral principles and common ownership of the land, was the only remedy against the deep moral crisis resulting from Westernization, which threatened Russia with a destructive revolution. Hence Russia should regenerate itself through returning to its old ways and bridging the gap between the educated classes and the common people. This was the conclusion of Aksakov’s long memoir *O vnutrennem sostoianii Rossii (On the Internal State of Russia)*, which he submitted to the new Tsar, Alexander II, in 1855 on his accession to the throne.

3 Ecclesiology and the concept of *sobornost’*

An important part of the Slavophile doctrine was its ecclesiology, developed by Khomiakov. It was an all-embracing theory of the Church as a divine-human organism. Its central concept, corresponding roughly to Kireevskii’s ’integrality’, was *sobornost’*. This term can be associated with both Church sobor (council) and the verb sobirat’ (to gather, unite). According to Khomiakov, the word *sobornost’*, which often occurs in old texts in Church-Slav, exactly corresponded to the Greek concept of ’catholicity’, which meant universal unity, the unity of all, personified in the Church council as an organ of the Holy Spirit.

Sobornost’, or catholicity, conceived in this way was a category which had an ecclesiological, social and epistemological meaning alike. Khomiakov derived its epistemological sense from the thesis that knowledge is rooted in will and faith, and these in turn depend on the strength of the bonds that link the individual to the Church community. The individual acquires knowledge of the truth only by uniting in love with the universal Church and thus becoming an organ of *sobornost’ soznaniia*, that is to say, supraindividual consciousness stemming from the charismatic unity of life. Separation from that community means entering the fatal road of rationalism and individualism. This was the case of the Church of Rome: by arbitrarily changing the Creed (the insertion of the Filioque) it raised the private opinion of Western bishops to the rank of a dogma, violating thereby the fundamental principle of catholicity. From that moment on unity and freedom became incompatible concepts in the West. The history of Europe changed into the history of ’unity without freedom’ (Catholic authoritarianism) and ’freedom without unity’ (Protestant individualism). The secret of the harmonious reconciliation of unity and freedom was preserved by the Orthodox Church, which remained faithful to the old Christian tradition of *sobornost’*. Hence the Orthodox Church had become the only universal Church, the only depository of the true ’catholicity’.

Khomiakov’s ecclesiology, systematically expounded in his treatise *The Church is One* and developed in a number

of polemical pamphlets and private letters (including letters to William Palmer, a member of the Oxford Movement whom he tried to convert to Orthodoxy), greatly differed from the standard views of the Russian Church hierarchy of his time. It was radically *pneumatic*, since it defined the essence of the Church as neither an institution, nor a doctrine, but as the charismatic community of tradition that covers all the faithful. It was *immanentist*, since it saw the inner consciousness of the Church as the only criterion of truth and categorically rejected the idea of authority. Its holistic and historicist character expressed itself in the denial that any local church (let alone an individual bishop) could be treated as the authoritative teacher. The whole truth, Khomiakov argued, is known only to the Church taken as a whole, including the laity; it crystallizes in an organic historical process, hence even the decisions of the Church councils need to be confirmed through becoming a part of the universally accepted tradition.

It is understandable that the hierarchy of the Russian Church saw in Khomiakov’s theological and ecclesiological works many dangerous ideas and (until 1879) strictly prohibited their publication in Russia. The Slavophiles, however, embraced these ideas with enthusiasm. Samarin wrote in 1867 that future generations would probably treat Khomiakov as a thinker who deserved to be called a Doctor of the Church. This prediction proved to be quite accurate. Despite dissenting voices (among them that of Father Pavel Florenskii), the prominent orthodox theologians of the early twentieth century (such as Father S.N. Bulgakov, Father G. Florovskii and many others) perceived Khomiakov’s views as the best insight into the true essence of Orthodoxy, an ’eyewitness account’ (Florovskii) of the reality of their Church. In many works Khomiakov is described as an important forerunner of the theological renewal in the Orthodox Church in the twentieth century (see Russian Religious-Philosophical Renaissance), or even as a Christian thinker who anticipated some ideas of the Second Vatican Council.

4 Ideological evolution and different continuations

Classic Slavophilism can be defined as a backward-looking utopianism, a Russian variant of conservative Romanticism, setting itself in opposition to the institutions and values of modern, capitalist civilization. Its utopian quality was not a matter for concern, since under the autocratic rule of Nicholas I no currents of Russian thought were allowed to be expressed in, and tested by, political activities. However, the loosening of political controls under Alexander II made it possible and necessary for the Slavophiles to pass from theory to practice. In these new conditions, Slavophilism was transformed into the right-wing variant of gentry reformism, on the one hand, and into Pan-Slavism, on the other. In both cases Romantic utopianism and emphasis on ’truly Christian’ values were replaced by an open commitment to nationalism, accepting, at least tacitly, the need for capitalist modernization of the Russian state.

The main Slavophile ideologists of the gentry-supported movement for reforms were Iurii Samarin and Aleksandr Koshelëv. They took an active part in the emancipation of serfs and because of this earned the reputation of ’liberals’, although their attitude towards Western liberalism remained intransigently hostile. The difference between them was that Samarin feared all forms of representative institutions on the national level while Koshelëv wanted an all-Russian Land Assembly with advisory power to be convened in Moscow, to serve as a counterpoise to the St Petersburg bureaucracy. Both men greatly contributed to the preservation of the village commune, defending it as a bulwark against proletarianization and as a supplier of cheap labour for the estates of the gentry. Samarin also became a leading ideologist of the russification policies in Russia’s ’western borderlands’ and in the Congress of Poland.

The leading figure in the transformation of Slavophilism into Pan-Slavism - an ideology providing ’Slav’ arguments for Russia’s territorial expansion - was Ivan Aksakov (younger brother of Konstantin Aksakov). He was an influential publicist, demanding the conquest of Constantinople and the establishment of a powerful, Russian-led Slav federation. His nationalism was anti-Semitic and violently anti-Polish, defining Poles as ’renegades of Slavdom’. More sophisticated and philosophically developed was the Pan-Slavism of Nikolai Danilevskii (1822-55), the author of *Russia and Europe* (1869). He grounded the ’Slav idea’ on a naturalistic foundation and developed an original theory of ’historico-cultural types’ of civilization, anticipating to a certain extent Spengler’s philosophy of history. But Danilevskii’s links with the founders of Slavophilism were very tenuous: he rejected their political Romanticism, especially the idea of a ’Christianization of politics’, claiming that Christian morality applied only to individuals, and that the relation of states and nations could only be based on self-interest and struggle for power (see Pan-Slavism §3).

The impact of Slavophile ideas on Russian thought was diverse and profound. The Slavophiles' views on the Russian peasant commune influenced Herzen and through him other ideologists of Russian populism. The Slavophile critique of the West was taken up by Dostoevskii and set the tone for all currents of Russian anti-Westernism. Slavophile philosophy, especially Kireevskii's 'integralism', was the main influence on Vladimir Solov'ëv in the first phase of his philosophical development; in later years he broke with the epigones of Slavophilism protesting against their nationalism and anti-Catholicism, but, none the less, continued to develop quite a few of their philosophical ideas. Russian religious philosophers of the early twentieth century had, as a rule, no doubts that Kireevskii and Khomiakov laid the foundation of a distinctively Russian tradition in philosophy.

Slovakia, philosophy in

Until as late as 1918, social and national circumstances were not favourable to the development of philosophy in Slovakia. The enforced retardation of the country had an obviously negative impact on intellectual and cultural life, and stood in the way of the possibility of diversity. That is why the first important Slovak philosophers such as Bayer and Caban emerged only as recently as the seventeenth century. Following this, philosophers of the Enlightenment such as Karlovský, Laurentzy, Steigel and Feješ started to criticize the anti-scientific ideas which still survived. In the first phase of the National Revival Movement, Jan Kollár created a new philosophy of history by postulating the cultural unity of the Slavs. A specific contribution to this theory came from L. Štúr and his followers (Hurban, Hodža, Kellner) who applied it to practical conditions and stressed the necessity of national emancipation for the Slovak nation. Their influence is evident in all further developments of the national movement and its philosophy.

The end of the nineteenth century saw the replacement of this idea by the philosophy of Thomas Masaryk. Slovak cultural life and philosophy, however, only began to develop fully in the context of an independent Czechoslovak Republic after 1918. The mainstream philosophy of the time was rationalistic, evident in the thought of such thinkers as Sv. Štúr, Koreň and Osuský. Philosophy after 1945 was marked by the achievements of Hrušovský, his students and colleagues, whose initial form of neopositivism took on a Marxist dialectical structurology. The importance of Marxism has recently been gradually declining and the Slovak philosophic scene is independently evolving in an atmosphere more in line with other European countries, particularly since the formation of the Slovak Republic in 1993.

1 History and evolution

As early as the tenth century, Slovakia lost its political independence during the formation of new states in the Danube valley. Subsequently, until 1918, Slovakia was politically subject to Hungary and later was part of the Austro-Hungarian empire. Under these circumstances the Slovak nation had lived through centuries of almost uninterrupted national, economic and cultural oppression by foreign rulers. The feudal atmosphere retarded cultural development, as well as the spread of higher education. Many Slovaks thirsting for knowledge went abroad - many of these never returned.

At the end of the sixteenth century the situation began to change as waves of humanism and later-Reformation thought arrived in Slovakia. The first humanistic scholars from Slovakia are connected with this period. These worked abroad, however, and included Ján Sambocký of Trnava (d. 1584), translator of Plato’s dialogues, Vavrinec Benedikti of Nedožiery (d.1615), educational reformer and propagator of the ideas of Petrus Ramus, and Ján Jessenius (d. 1621), physician and supporter of Renaissance Neo-Platonist natural philosophy.

2 The seventeenth to nineteenth centuries

The Reform School (*kolegium*) in the East Slovak town of Prešov became the country’s first important philosophical centre. This school tried to overcome scholasticism by promoting Bacon’s inductive empirical methods, thereby hoping to achieve closer connection between philosophy and the natural sciences (see Bacon, F.). The leading representatives, who were influenced also by the works of Comenius, were Ján Bayer (d. 1674) and Izák Caban (d. 1707). At the Jesuit university in Trnava, centre of the anti-reform movement, some professors, including František Kéri (d. 1768), Andrej Jaslinský (d. 1784), and Ján B. Horvát (d. 1800), were impressed by the methods of current natural science and worked to free Slovak philosophy from orthodox neoscholasticism.

The Enlightenment reached its peak in Slovakia between 1789 and 1820. Here it showed some indications of compromise (particularly in relation to religion) when compared to its western European counterpart. Nevertheless, it also fulfilled an emancipatory function through figures such as Žigmund Karlovský (d. 1821), Ján Laurentzy (d.1819), Michal Steigel (d.1829), and Ján Feješ (d.1823).

National Revival, developing at first in parallel and in cooperation with similar Czech feelings, brought a change in the orientation of philosophy. Abstract metaphysics, ontology and logic were no longer at the forefront. Their place was taken by philosophy of history, an interest in theories of nationhood (in connection with philosophy of language, arts and culture) and, in general, philosophy conceived as the theory of particular social practices.

Reform tradition, German neohumanism and philosophers such as Herder, Fries and Hegel stimulated new thought. Theoreticians of the National Revival saw ideological support for their efforts in the ‘Slavonic’ emergence of Herderian-Hegelian philosophy of history as the highest degree of human development. Ján Kollár (d. 1852) built on this philosophy to produce his own idea of the mutual cultural evolution of Slavs. L’udovít Štúr (d. 1856) developed the idea in a Hegelian spirit by stressing the necessity of a specific emancipatory role for the Slovak nation, thus influencing the whole future course of the Slovak national liberation effort. Štúr’s contemporaries and followers put forward similar ideas, and this concept achieved a kind of Slavonic messianicism in the thought of some philosophers.

A change is evident in the second half of the nineteenth century with thinkers interested in the particular needs of national society. This work was undertaken by scientists such as D. Štúr, A. Stodola and J.A. Wagner on the one hand, while on the other there was later, from the beginning of the twentieth century, a group of intellectuals, including V. Šrobár, A. Štefánek and J. Lajčiak, gathered round the magazine *Hlas* (Voice) which was inspired by the philosophy of Masaryk.

3 Twentieth century philosophy

When Slovakia became part of the independent Czechoslovak Republic in 1918, a new situation arose. Slovak intellectual life flourished and became the potential repository of a new philosophical culture. Contact with the more progressive Czech philosophy became more intensive (Czech philosophers lectured at the newly founded university in Bratislava). Direct contacts with contemporary European thinkers also increased. The influence of Masaryk’s philosophy continued to be strong, particularly in the work of Svätopluk Štúr who also made use of ideas from Benedetto Croce and J.L. Fischer in his search for a synthetic type of rationalism. Classical positivism prevailed in the work of Jozef Koreň and Samuel Š. Osuský, ideologically influenced by the Protestant tradition.

An important event in Slovak intellectual life was the establishment in 1937 of the Association for Scientific Synthesis which brought together researchers from different scientific fields. This association emphasized the use of methodological principles taken from neopositivism and structuralism. The leading figure was Igor Hrušovský who, even after accepting the basic theses of Marxism after 1945, remained the dominant figure of Slovak philosophy, and created a new concept of dialectical structurology.

When the Communist Party regained power in 1948, a Marxist orientation was enforced and subsequently dominated public Slovak philosophy. Historians of philosophy such as E.Várossová, T. Münz, J. Bodnár, J. Kocka, M. Burica, M. Zigo and others began to free themselves from ideological oppression, and many published valuable works. These were followed by works of authors from other philosophical disciplines, and Slovak translations of philosophical classics achieved important success.

After 1968, in the period of the totalitarian regime, philosophers Milan Šimečka and Miroslav Kusý worked in the dissident movement. Their works, analysing the problems of the time, were published illegally or abroad. In the 1980s, the younger generation of Slovak philosophers began publishing the results of their research on the history of philosophy, the problems of phenomenology, existentialism, analytic philosophy, the Frankfurt School and also on postmodern trends. However, it was only after the fall of the totalitarian regime in 1989 that complete freedom of philosophical activity became possible.

Smart, John Jamieson Carswell (1920-)

J.J.C. (Jack) Smart was born in England and studied at Glasgow and Oxford universities before moving to Australia to take up the Chair of Philosophy at Adelaide University. He was one of the earliest and most influential advocates of the mind-brain identity theory, the view that mental states are identical with brain states. He also played a major role in articulating and defending realism in science, the four-dimensional view of time and act utilitarianism in ethics.

1 Biography

J.J.C. Smart was born on 16 September 1920 in Cambridge, England. At Oxford he was influenced by Gilbert Ryle though he subsequently abandoned Rylean behaviourism in favour of a robust realism about mental states and scientific entities. He took up the Chair of Philosophy at Adelaide University in 1950, and moved to La Trobe University in 1972 before going to the Chair of Philosophy at the Institute of Advanced Studies at the Australian National University in 1976. He has made a number of visits to the United States and probably has had more philosophical influence there and in Australia than in Britain.

A distinctive feature of his writing is the clarity and directness with which he advances his views. This is a trait that he shares with another important Australian philosopher, David Malet Armstrong, and together they have influenced the way a generation of philosophers in Australia write, as well as influencing the doctrines they espouse.

2 Mind-brain identity theory

In a landmark article, ‘Sensations and Brain Processes’, first published in 1959, Smart defends the view (put forward earlier by his Adelaide colleague U.T. Place) that sensations are brain processes. Sensations are not correlated with or causally connected to, but literally identical with brain processes in the same way that lightning is identical with an electrical discharge. Later he extended the view to encompass intentional states like belief and desire and mental states in general.

An important feature of his version of the identity theory is his topic neutral analysis of sensation reports. He grants that when I report a sensation in a sentence like ‘I am in pain’ or ‘I am having a yellow after-image’, I am not making a claim about my brain as such. I may not even know that I have a brain. I am, he argues, making a claim roughly to the effect that something is going on in me like what goes on in me when a pin is stuck in me or a whip is applied to me or … (in the case of pain), and like what goes on in me when I see a lemon or a sunflower or … (in the case of a yellow after-image). The nature of these ‘somethings that go on in me’ is then a matter for empirical investigation, and his view is that they will turn out to be certain processes in the brain. With the benefit of hindsight we can now see his topic neutral analyses as a precursor of functionalism, for both see mental states as inner states whose mental nature is a matter of their relational properties (see Mind, identity theory of; Functionalism).

3 Realism, time and ethics

The view that mental states are brain states is a species of realism. Mental states are not ‘convenient fictions’ for the prediction of behaviour. Similarly, Smart argues that the sub-microscopic particles of physics are real. Electron theory is not merely a device for predicting the tracks in Wilson cloud chambers (see Fictionalism; Scientific realism and antirealism). Electrons rather are the causes of these tracks. Otherwise, Smart argues, the regular appearance of the tracks would have to be regarded as a cosmic coincidence. More generally, he argues that only the realist can explain why positing sub-microscopic particles should have such great instrumental value. Smart insists that the situation with electrons and macroscopic entities like tables and the sun is essentially the same: none is to be reduced to patterns of observations or patterns of experiences. They are all independently existing entities to be believed in as the best explainers of the patterns.

Smart views time as a fourth dimension akin to the three spatial ones, and sees this as the only view to hold in light of the Minkowski interpretation of relativity theory. Objects are extended in time as well as space, and accordingly have temporal parts as well as spatial ones. A tree’s growing is a matter of later temporal parts of the tree being

taller than earlier ones, and the problem of identity over time - of persons, trees, schools or whatever - becomes the problem of finding the right relation to unify different temporal parts to make up a single, temporally extended person, tree, school, or whatever. On this view the present has no special ontological status: what I call ‘now’ is simply the time of my calling, and the past is simply times before then, and the future times after then.

Smart’s position in meta-ethics is a version of noncognitivism: ethical statements are expressions of overriding attitudes, and words like ‘good’ and ‘right’ are terms of commendation, not terms that describe (see Emotivism). His position in normative ethics is an uncompromising version of act utilitarianism. The right act is that act out of those available to the agent that would produce the most happiness (or, better, has the greatest expectation of doing so). He famously criticizes rule utilitarianism - the view that the right act is the act in accord with the rule the following of which would produce the most happiness - as involving a kind of ‘rule worship’ inconsistent with utilitarianism’s guiding thought that it is outcomes that matter. In Smart’s view the value of keeping promises, distributing goods equitably and not punishing innocent people, is instrumental only. Thus, in (arguably rare) cases where punishing someone innocent would have good results - perhaps it is generally believed the prisoner is guilty so that punishing him would have a deterrent effect on potential wrongdoers - it is straighforwardly right to do so (see Utilitarianism).

Smith, Adam (1723-90)

Despite his reputation as the founder of political economy, Adam Smith was a philosopher who constructed a general system of morals in which political economy was but one part. The philosophical foundation of his system was a Humean theory of imagination that encompassed a distinctive idea of sympathy. Smith saw sympathy as our ability to understand the situation of the other person, a form of knowledge that constitutes the basis for all assessment of the behaviour of others. Our spontaneous tendency to observe others is inevitably turned upon ourselves, and this is Smith's key to understanding the moral identity of the individual through social interaction. On this basis he suggested a theory of moral judgment and moral virtue in which justice was the key to jurisprudence. Smith developed an original theory of rights as the core of 'negative' justice, and a theory of government as, primarily, the upholder of justice. But he maintained the political significance of 'positive' virtues in a public, non-governmental sphere. Within this framework he saw a market economy developing as an expression of humanity's prudent self-interest. Such self-interest was a basic feature of human nature and therefore at work in any form of society; but commercial society was special because it made the pursuit of self-interest compatible with individual liberty; in the market the poor are not personally dependent upon the rich. At the same time, he recognized dangers in commercial society that needed careful institutional and political management. Smith's basic philosophy is contained in The Theory of Moral Sentiments (1759), but a major part concerning law and government was never completed to Smith's satisfaction and he burnt the manuscript before he died. Consequently the connection to the Wealth of Nations (1776) can only be partially reconstructed from two sets of students' notes (1762-3 and 1763-4) from his Lectures on Jurisprudence at Glasgow (Smith [1762-6] 1978). These writings are complemented by a volume of essays and student-notes from lectures on rhetoric and belles-lettres.

Although a philosopher of public life and in some measure a public figure, Adam Smith adhered to the Enlightenment ideal of privacy to a degree rarely achieved by his contemporaries. He left no autobiographical accounts and, given his national and international fame, the surviving correspondence is meagre. The numerous eyewitness reports of him mostly relate particular episodes and individual traits of character. Just as there are only a few portraits of the man's appearance, there are no extensive accounts of the personality, except Dugald Stewart's 'Life of Adam Smith' (1793), written after Smith's death and designed to fit Stewart's eclectic supplementation of common sense philosophy. While Smith was a fairly sociable man, his friendships were few and close only with men who respected his desire for privacy. David Hume was pre-eminent among them.

1 Life

Adam Smith's date of birth is unknown, but he was baptized in Kirkcaldy in Fife, Scotland, on 5 June 1723. His father, a customs officer, died some months earlier and Smith was brought up as an only child, a circumstance shared with several contemporary Scots literati, as has been emphasized in recent psycho-history (Camic 1983). Smith evidently remained close to his mother., and some will see this as an explanation for the fact that his attraction to female company never stretched to marriage. Otherwise, we have little evidence of the nature of Smith's intimate life.

As was common, Smith attended the local parish school and then went to Glasgow University in 1737, where he was taught moral philosophy by Francis Hutcheson. In 1740 he went to Balliol College, Oxford, lingering there for six years. He compensated for the lack of organized education - later condemned in the *Wealth of Nations* (1776; henceforth *WN*) - by extensive private study, mainly in Greek, Latin and French literature, turning himself into an extremely well-read man. From 1746-8 Smith seems to have stayed with his mother in Kirkcaldy; but during the following three winters he gave public (non-university) lectures in Edinburgh, sponsored by Henry Home (later Lord Kames) and his circle. The lectures were on rhetoric and belles-lettres, to which was eventually added a series of lectures on jurisprudence (published subsequently as *Lectures on Jurisprudence* ([1762-6] 1978; henceforth *LJ*)). This performance had the desired effect; in 1751 Smith was appointed professor at Glasgow University, first in logic and, after one year, in moral philosophy. Until his resignation in the middle of 1763-4, Smith gave the basic course in moral philosophy that had been founded by Gershom Carmichael in the 1690s and developed by Francis Hutcheson in the 1730s and 1740s. It encompassed natural religion, ethics and jurisprudence. In addition, Smith gave an advanced class on rhetoric and belles lettres. Hardly a trace of Smith's lectures on

natural religion has survived, but those on ethics formed the basis for his first major work, the *Theory of Moral Sentiments* (1759; henceforth *TMS*). Two student-reports on the lectures on jurisprudence, which include economics, have survived from 1762-3 (incomplete) and 1763-4 (henceforth *LJ*(*B*) and *LJ*(*A*), respectively); see Smith 1762-6: there is also the fragment of a report from earlier in Smith's career ('Anderson Notes'). Finally, there is a student's report on the lectures on rhetoric and belles-lettres from 1762-3 (henceforth *LRBL*; see Smith 1762-3).

Early in 1764 Smith became travelling tutor to the Duke of Buccleuch, a lucrative post that afterwards gave him a pension and an influential connection for life. Travelling in France and Switzerland until 1766, Smith met many of the French Enlightenment's leading thinkers, notably François-Marie Arouet Voltaire and the circle of physiocratic economists led by François Quesnay and Anne Robert Jacques Turgot. Smith admired Voltaire, especially as a dramatist; and he shared the conceptual, empirical and normative concerns of physiocracy, though he reached different conclusions about these matters. Like the physiocrats, he understood the relationship between economics and civil society by postulating ideal-typical stages of social development; and like them, he rejected the common mercantilist analysis of wealth in terms of money and advocated a free economic system to create such wealth. Smith, however, rejected the physiocratic idea of land as ultimate source of wealth.

Smith had begun working on these matters during his Glasgow years, as *LJ* and the 'Early Draft' of the *WN* (reprinted in *LJ*) show. But it took him nearly another decade to develop his own grand theory. He worked until 1773 in seclusion at his mother's house in Kirkcaldy and then spent three years in London revising his manuscript. The *WN* appeared in the spring of 1776 to resounding praise from David Hume and Edward Gibbon, among many, and quickly turned the distinguished moral philosopher into a famous political economist.

1776 was in another respect a turning point for Smith, for in the late summer David Hume died. This led Smith publicly to indicate his religious outlook more clearly than before. He was already assumed, as we see from the cool attitude of James Boswell (once Smith's student) and Samuel Johnson, to be a sceptic concerning revealed religion. But when Smith publicly maintained that the infidel Hume had approached 'as nearly to the idea of a perfectly wise and virtuous man, as perhaps the nature of human frailty will permit', he was widely taken to have declared his own atheism (1777: xlix). In fact, Smith never made explicit his religious beliefs. Much of his work appears to be in the mould of common deism, but often it is unclear whether Smith is analysing deism as a psychological disposition or whether he is accepting it as a doctrine. In the end his obdurate silence suggests he had accepted the basic lesson of agnosticism. He seems cooler toward religion as he gets older, and his 'obituary' for Hume is a milestone on this road.

In 1777 Smith was appointed Commisioner of Customs in Edinburgh, a lucrative office that he discharged conscientiously until his death. In addition to being in public office, Smith was now a public man of letters, sought by government and politicians for advice on matters of state and policy, such as relations with America and Ireland, trade and taxation. He had been elected to the Royal Society and to the Johnsonian 'The Club' during his stay in London in 1773-6. When he paid a rare visit to London, he was received in the literary circles around the Oyster Club, and although he never ventured abroad again, he remained a name in the Parisian salon-world, where he had been so well received in the '60s. He was also part of the cultural life of the high Enlightenment in Edinburgh, sought out by literary tourists and opening his house to a circle of friends once a week (see Enlightenment, Scottish). True to his suggestion that a citizen militia served a moral purpose, he was an officer in the Edinburgh militia. Smith lived with his mother, his cousin, Janet Douglas, and a nephew of the latter, David Douglas, whom Smith made his heir.

During these years Smith kept writing. He revised the *TMS* several times, including a major recasting (6th edn 1790) shortly before his death. The *WN* was revised for the second and, especially, the third editions (1778 and 1784) and saw two more life-time editions. But Smith also undertook new projects. One was a 'sort of theory and history of law and government', announced already in the first edition of *TMS* and still aspired to in the last edition of that work. The *WN* had taken account of 'police, revenue and arms', but the part concerning justice, the theory of jurisprudence, was still lacking (*TMS*, Advertisement: v). Smith's other project was 'a sort of Philosophical History of all the different branches of Literature, of Philosophy, Poetry and Eloquence' (Smith 1977: 287). A few days before he died, Smith requested his sixteen manuscript volumes to be burnt. We can form some idea of the former project from the lectures on jurisprudence and parts of *TMS* and *WN*; the latter was obviously related to the

early *Essays on Philosophical Subjects* (henceforth *EPS*), published posthumously in 1795, and to the Glasgow lectures on rhetoric and belles lettres. But the systematic coherence of Smith's work is a matter of reconstruction - some scholars even deny that it has such coherence, despite Smith's declared intentions. Smith died in his house in the Canongate on 17 July 1790 and is buried in the Canongate cemetry.

2 Imagination: scientific and moral order

The single most important influence on Adam Smith was David Hume's philosophy, especially the theory of the imagination as the active mental power that fashions a specifically human world within nature (see Hume, D.). Like Hume, Smith saw imagination as that which enables us to create connections between the perceived elements of both the physical and the moral world, ranging from particular events and things to the cosmos and the system of humanity. For Smith there are two fundamentally different kinds of imagination, one concerning other persons as agents and one concerning things - human beings included - and events. The former is the basis for personal identity and sympathy (in Smith's special sense) and, thus, for the moral world. The latter is the basis for all theoretical activity of the mind, including science and the arts. The activity of the imagination is a spontaneous search for order and coherence in the world; satisfaction of it carries its own pleasure, while frustration brings 'wonder and surprise' and, if prolonged, anxiety and unease. Smith talks of this imaginative striving in aesthetic terms as a concern with beauty and harmony.

The 'theoretical' imagination is invoked for a number of different explanatory purposes. It accounts, according to Smith, for our ability to order things and events so that we can orient ourselves in life. It explains the 'aesthetics' of ordinary living, such as our tendency to order things for no other purpose than the order and arrangement that please, and our desire for machinery, gadgets and other 'systems'. Works of art, as well as of technology, are works of imaginative order. Not least, philosophy and science are products of the imagination's attempt to create order in the chaos of experience. This is expressed in the recurring machine analogies for the natural world and for society; and it is reflected in the human mind's tendency to underpin the perceived orderliness of the world by assuming an orderer with a purpose. In other words, science, deism and natural providence are all parts of the explanatory web that the imagination creates to satisfy its desire for order.

Within this framework Smith writes his remarkable histories of science, notably the essay on the history of astronomy. The basic thesis is that empirical evidence can only play a role as evidence if it fits into an orderly system of beliefs. Smith exhibits a sceptical distance in relation to all absolute truth-claims in both science and religion, epitomized in the famous conclusion to 'The History of Astronomy' in *EPS*:

> [Newton's] principles, it must be acknowledged, have a degree of firmness and solidity that we should in vain look for in any other system. The most sceptical cannot avoid feeling this… And even we, while we have been endeavouring to represent all philosophical systems as mere inventions of the imagination, to connect together the otherwise disjointed and discordant phaenomena of nature, have insensibly been drawn in, to make use of language expressing the connecting principles of this one, as if they were the real chains which Nature makes use of to bring together her several operations.
>
> ([1795] 1980, IV.76: 105)

When we introduce order into our observations of other people, as opposed to the rest of nature, our imagination takes on a special quality. We are able to 'make sense' of the behaviour of others through imaginative identification - what Smith calls sympathy, a central concept in his philosophy. 'Sympathy'here has no evaluative connotations; it does not mean that one person accepts the motives and actions of another as good and right, nor is it a motive for action. Sympathy is the ability to see the point of view of another person so as to be able to accept or reject it as appropriate in *that* person's situation. This native ability is the key to Smith's social theory of the self and, through that, to his theory of the moral world.

Inclination and need lead people to interact; interaction depends on observation and appreciation of others and their situation, and this is facilitated by the universal tendency sympathetically to adopt the position of the other and compare reactions. Observation of others will bring awareness that oneself is the object of other people's observation and assessment. Society is the mirror in which individuals see their own nature. Further, in observing that one is being observed one has the basis for such mutual adjustment of behaviour as is necessary for all social living. Each individual is generally led to pre-empt this assessment by others through self-observation and

self-assessment. In short, people internalize the spectator, and the internal spectator has the force to prompt such adjustment of behaviour as would otherwise be demanded by external spectators in order to satisfy the inclination to, or the need for, agreement or conformity.

The process of mutual adjustment through the sympathetic search for a common standpoint often fails, of course, leading to moral and social disorder. Thus we are led to imagine an ideal judgment and an ideal judge, transcending the limitations of knowledge, bias, and so forth of those actually involved. Once we establish a dialogue with this imagined ideal of an impartial spectator, we have a moral conscience.

With this social theory of moral personality Smith rejects the idea of Hutcheson and others that moral agency hinges on a special moral sense, offering instead explanations based on empirical features of the mind. Like Hume, Smith rejects the suggestion of Samuel Clarke and others that moral judgment and motivation are forms of rational inference. And he ignores religious ideas of conscience as infusion (inspiration) by the deity or a response (fear) to the deity's might perceived. For Smith, formation of the moral self begins with others.

3 Moral theory

By means of this theory of the self, Smith produces a complex analysis of moral life. Moral judgment is inevitably an assessment of propriety - first of the motives of an agent in a given situation, then of the motives of the person who is the 'object' of the agent's actions. But our inclination towards orderliness leads us to classify actions just as our search for impartiality suggests general and impersonal points of view; and on this basis we develop general rules of behaviour which, once given social acceptance, significantly influence our assessment of the propriety of particular motives and actions. Sympathy ties us to the particularity of the situation, while the impartial spectator calls for the generality of rules. Similarly, while we have great difficulty making a moral assessment of motives and associated behaviour on the basis of their outcome, we tend to allow utility and disutility to influence our perception of propriety.

In a different mode from that of the analysis of moral judgment, Smith gives a complex account of moral virtue. At one level he looks on the moral and social ideas that make the world go round from the elevated standpoint of the stoic sage (see Stoicism §19). Smith was attracted by the stoic ideal of tranquility as the end of moral life; yet his account of moral psychology showed everything distinctive about the life of the human species to be due to people's inability to live in tranquility. The exercise of our productive powers, as portrayed in the *WN* and in the *TMS* as emulative vanity, is only the most dramatic illustration of an inescapable restlesness pervading our lives. In Smith's view a dialectic tension between tranquility and activity is bound to be a permanent feature of human life, and the implication is clearly that it would be futile for the philosopher to attempt to defend the one over the other.

At another level, Smith looks at morality from an historical point of view, and combines this with a theory of the cardinal virtues. The features of personality and courses of action people approve and disapprove of in others and in themselves vary from one culture and period to another. Accordingly, a major task for philosophy is to look at humanity historically and comparatively. This reveals that in one sphere of human response there is a great deal that is common to all humankind, namely in the sphere of *moral* approval and disapproval (as opposed to, say, the aesthetic or religious response). The moral philosopher can identify a number of basic virtues and vices, the tone and composition of which may vary significantly, but which are nevertheless universally recognizable and comparable.

One way of organizing this field is by means of the cardinal virtues, though Smith, like Hume, is more interested in distinguishing 'positive' from 'negative' virtues, - benevolence from justice. The distinction is based upon spectator reactions. When the spectator, whether the actual or the imagined impartial one, sympathetically enters into the situation of an agent, the result is approval or disapproval of the agent's judgment and action. When the agent tries to promote the good of someone, whether of self or of other, the spectatorial approval or disapproval tends to vary from person to person. For while we tend to agree on what is good in broad outline, we have great difficulty agreeing on what is good for particular persons in specific situations, unless we are connected in some moral community. By contrast, we tend to agree on what is harmful not only in general but in each case, and the pattern of reaction to harmful behaviour therefore has a high degree of uniformity, known as resentment.

4 Law and politics

The negative virtue of avoiding harm or injury is, according to Smith, *justice*, which is the foundation of law and the subject of jurisprudence. The positive virtues encompass the life of the private sphere, but, in addition, they are the basis for a public sphere that is neither political nor administrative in modern terms. By maintaining a system of justice, the government protects both private life and the non-political public sector of human activity, and one of the most striking features of the modern world of commerce is, in Smith's eyes, that by doing so government has made it possible for economic behaviour to be transformed from private to public.

The personal attributes and actions that are protected in each person when others show them justice, that is abstain from injuring them, are their rights. A *right* is a sphere of freedom to be or do or have something that the individual can maintain against all others because the spectatorial resentment towards infringement of this sphere is so strong that it has been institutionalized in the form of the legal system. This line of argument puts Smith in a tradition of thinking about rights that goes back to Grotius, Hobbes and some religious covenanters. In this tradition the primary moral characteristic of the individual is self-assertion *vis-à-vis* the rest of humanity, so that all common or social morality arises through 'negotiation' between conflicting claims. Natural *law* is a secondary concept to that of *right,* in contrast to the ideas of the mainstream of thinking about natural law. While Hume was in some respects close to this tradition, he never found a way of accommodating the concept of rights within his sentimentalist theory of morality. This was left to Smith's theory of the spectatorial regulation of our moral sentiments (see Natural law; Rights).

'Rights', 'injury', and 'personality' are linked. The imagination depends on social experience and hence varies from one stage of society to another; consequently the idea of moral personality must vary. This is the core of Smith's historical approach to justice and law. Smith rejects the idea of a state of nature as a device for understanding human nature. The moral life of the species is unavoidably social, since only the social mirror lends us humanity. All consideration of our moral characteristics must therefore include the social setting; this applies not least to rights as the primary characteristic. Even so, certain minimal rights are universal to all social living. A social group is only viable if it recognizes rights to physical, moral and some kind of social personality; these may accordingly be considered universal, 'natural' rights. Beyond this minimum, we have to look to the historical circumstance in order to understand rights.

In Smith's view, humanity can be divided into four broad stages of social development according to the extension of the concept of the person and, consequently, the scope of rights recognized. Hunters and gatherers recognize little beyond what immediately sustains the physical and moral person (food, shelter, personal freedom and social recognition). Dramatic extensions of personhood are produced by nomadic 'shepherds', with the recognition of property in food and tools much beyond what is required for each individual and their immediate dependents; and, further, in the agricultural stage, with recognition of property in land. The most abstract extension of the concept of personality occurs in commercial society, with the full development of contractual entitlements and ownership of purely symbolic property (paper money, credits) as parts of what a person is.

Each of these developments requires stronger government to protect its new rights, and, accordingly, the four-stages theory also accounts for the growth of government and law. However, the four stages are not to be understood as the actual steps of the past; they are 'ideal types'. The historical past has deviated greatly from this conjectural model, mainly due to forceful and tyrannical behaviour by rulers and conquerors. The modern world was thus, for Smith, decisively shaped by the emergence of commerce before agriculture was properly developed, due largely to an alliance of monarchs and city-burghers forged for the purpose of breaking the power of feudal nobility. The resulting alliance of modern government with commerce and finance is the unholy alliance targeted in *WN*.

The *WN* is the greatest working-person's tract ever written. Central to its argument is that in the modern world even the working poor can enjoy personal liberty because the modern economy enables them to sell their labour without selling themselves. With the deepening of the division of labour, each piece of work becomes more 'abstract', less tied to personal abilities, and more easily assessed in monetary terms. The labourer can therefore sell his labour-power to anyone, without the personal dependence of traditional service-relationships. But this will only be effective if the labourer's freedom to sell his labour is protected by government as a right, against traditional monopolistic restrictions.

The liberation of labour from 'servility' is central to the transformation of productive life from the private, familial sphere to the public market, from household oeconomy to political economy. This can only take place when the immoral exaggeration of the virtue of prudent self-interest, namely avarice, can be rendered innocuous in the eyes of society. This happens when the problem of distribution begins to be solved through the market. In pre-commercial society, owners can only use their property by consuming it, and this they can do only by maintaining dependents, typically in the extended family. In commercial society they can spend their riches via the anonymous other of the public market. Accumulation of wealth becomes not only compatible with but dependent upon the freedom of the poor, which leads to a distribution of goods that, while unintended, is as equal as is realistic among humanity.

> [The rich] are led by an invisible hand to make nearly the same distribution of the necessaries of life, which would have been made, had the earth been divided into equal portions among all its inhabitants, and thus without intending it, without knowing it, advance the interest of the society, and afford means to the multiplication of the species.
>
> ([1759] 1976, IV.1.10: 184-5)

There is a price for this freedom, namely the danger of moral corruption. The rich are constantly tempted to undermine the system that creates their wealth by seeking protection against competition. And the poor are exposed to the stupification of mechanical work, rendering them incapable of taking charge of their lives and making them useless as citizens and soldiers. In both areas protection is to be sought from government; in the former through anti-monopoly legislation and policy, in the latter through basic education funded in part by the public and through freedom of religious worship, both of which tend to establish a moral community of spectators within which the labourer can develop a moral character.

In addition to the economy that springs from self-interest, and the system of law that institutes the virtue of justice, Smith thus operates within a purely political sphere. Politics concerns 'police, revenue and arms', which means various municipal services and major construction works that the market cannot provide, and which facilitate commerce, plus defence. But under 'revenue' Smith also includes educational and cultural policies that are concerned with 'positive' virtues, or at least with facilitating such virtues. Smith is wary of stretching this function of government too far, because of the danger of tyranny in enforcing specific ideas of the good life. This, however, is not the limit of the role of positive virtue in public life: it extends also into an important public, non-political sphere.

Smith has much to say about the importance of a wide variety of social virtues - liberality, probity, generosity, courage, leadership, indeed justice in a distributive sense; or 'public spirit', as he often sums it up. But while these are virtues associated with public office, they are not the virtues that provide the very rationale of government in the way that justice does. Nor are these desirable qualities simply the private virtues of public figures, though they are certainly also that. Integral to Smith's society was a public sphere that was in some sense political, yet was not governmental. This was the world of the local elite, lairds and landlords with significant leadership in local affairs that today are matters of public policy. At the pinnacle of this world were the members of Parliament, whose work overwhelmingly consisted in dealing with private members' bills - often concerned with local matters - rather than with the business of executive government. The proper basis for these public roles was provided by the kind of positive virtues indicated above. While Smith wanted to exclude, or at least severely limit, these virtues in the function of government proper, he never doubted their essential role in a non-political public sphere. Today this sphere has largely been subjected to politics in a development that Hegelians might think of as the politicization of civil society; but it is anachronistic to use this sense of civil society in reading Smith: the public virtues and behaviour he is concerned with are not defined *vis-á-vis* the state.

Smith was not simply an advocate of a particular political and economic scheme. From his Humean perspective, there was little point in advocating things unless they were within the limits of people's imagination. The task was to extend that imagination by informing it of the full complexity of its situation. People who are thus informed may become impartial in judging their society. Smith had educated himself to be an impartial spectator who saw the injuries or injustices done to classes of people in the name of political exigencies that had long since passed. An appeal to the universal virtue of negative justice and an explanation of how and why it was being infringed in this particular historical situation was therefore the backbone of his history and theory of law and government; but he

did not thereby reduce all moral life to the administration of justice. At his best he combined the psychological perspicuity of Jane Austen, the historical richness of Gibbon and the philosophical acumen of Hume.

Social action

Most of our actions take place in a social context and are, accordingly, in one way or another, dependent on the existence of other persons and their relevant actions, social institutions, conventions, or the like (for example, saluting, voting, drawing money from one's bank account, using lipstick, buying something). But people also perform actions jointly or collectively, to achieve some joint goal. Thus they may jointly sing a duet, play tennis, build a house, or conserve energy. This is collective social action in its most central sense. Such action is based on the participants' mutually known joint intention ('joint plan') to perform it. In weaker kinds of collective social action the participants are interdependent - as to their actions or thoughts - in some other ways.

This entry shall concentrate on collective social action, indeed on the central case: joint action based on joint intentions. Thus, you and I may form the joint intention to paint the house together and agree upon some method of doing it, for instance, that you paint the front while I paint the back of the house. We also agree upon which paint to use and other similar things. Carrying out our joint intention, we come to paint the house jointly. This kind of intentional joint action can be characterized more generally as follows, taking a joint action to be an action divisible into single-agent parts, that generate a purported outcome: the participants have formed a joint plan for a joint action; the plan is taken to involve a relevant joint intention, entailing for each participant the intention to perform their part of the joint action. The participant is assumed to believe that the various conditions for the success of the joint action will be fulfilled at least with some probability, and also to believe that this is mutually believed by the participants. The performance of a joint action can be regarded as agreement-based if the plan has been accepted by the participants and if they have appropriately communicated their acceptances to the others so that a joint obligation to perform the joint action has come about. Joint action in the fullest sense can be argued to be based on either explicit or implicit agreement (in a wide sense) (see Intention).

Over and above the standard sense of joint action based on the participants' joint intention we may also speak of joint action in a somewhat wider sense not necessarily involving joint intention. For example: some persons, seeing a car starting to slide down a hill, together start pushing it up the hill. I am passing and form the intention to push the car together with the others, an intention with a collective action as its content, and take part in the pushing. There may even be a belief among all the pushers that I also am participating. All this can take place without these car-pushers (or at least all of them) having a joint intention (joint plan) to push the car together with the others. So understood, we do not have here more than joint action in a wide sense - namely joint activity based on shared collective intention but not full-blown joint intention. The participants' intentions, when the participants are mutually aware of them, can still be regarded as social attitudes ('we-attitudes' in the sense of Tuomela 1994). Ideally, a person has such a social attitude (for example, an intention to do something together) relative to their group if and only if they (1) have (or share) this attitude, (2) believe the group members have it, and also (3) believe that there is a mutual belief that the members have this attitude. The broadest sense of joint action can be taken to be collective action performed because of a shared social attitude.

Joint action in this wide sense excludes such 'mere co-action' as people acting simultaneously in the direction of the same goal but (possibly) independently of each other (for instance, Max Weber's example of people simultaneously opening their umbrellas when it starts to rain). Such co-action does not deserve to be called social action at all.

We can, however, include among social action the following two kinds of collective action with social features - although they do not quite amount to collective social action in our previous sense:

(1) Collective action which is merely accompanied by (but not performed because of) a social attitude (we-attitude). The participants may be performing an action (for example, selling shoes at a department store) either separately or 'together' as their parts of a collective project (or believed project), planned or structured by them or by somebody else.
(2) Collective action consisting of separate individual actions directed towards and performed because of a shared, possibly merely personal goal (the realization of which normally requires several agents' participation).

In the literature on collective action either social action in the strict sense or cases of the kind (1) and even of the

kind (2) may be involved. In those cases there is often a public good to which individual actions contribute, although they normally are relatively costly to the contributors. It is worth noting, too, that the interaction (either ‘parametric’ or ‘strategic’ interaction) is typically present in joint action in the wide sense and sometimes also in cases of the kinds (1) and (2).

The participants’ preference structures in a joint action can be fully cooperative (for example, carrying a table) or they can be to some extent noncooperative (for example, chess, buying and selling). Furthermore, joint action can be physical (for example, carrying a table) or it can involve a conventional or normative element such as transfer of rights (for instance, toasting a national victory, making a business deal, getting married).

Joint action as collective action performed because of a social attitude and social action in the broader senses (1) and (2) are all cases of collective social action and seem to make the classification exhaustive.

Social choice

Social choice theory is the branch of economics concerned with the relationships between individual values, preferences and rights and collective decision making and evaluation. Social choice theory therefore provides connections between the formal analysis of rational choice, the debate on political process, and ethics. A central theme in social choice theory has been the aggregation of individual preferences into either a social decision rule or a social evaluation rule. The most famous result in social choice theory - Arrow's impossibility theorem - is that such aggregation is impossible if individual preferences are conceived as ordinal in nature, and if the aggregation procedure is to satisfy certain apparently reasonable conditions. This result implies that neither a voting system nor a system of moral evaluation can be found that satisfies all of the required conditions. Further impossibility theorems arise from attempts to model the role of individual rights.

Much of social choice theory is concerned with interpreting, extending and questioning these impossibility theorems in a variety of contexts. This discussion has generated an extensive interchange at the margins of economics and ethics on topics such as the commensurability of values and the relationship between morality and rationality.

1 Impossibility theorems

Arrow's theorem concerns the aggregation of a set of individual orderings to form a social or collective ordering. The word 'ordering' is used in its technical sense to indicate an ordinal relation that is reflexive, transitive and complete. The objects of the ordering are not specified by the theorem but, following Arrow, social choice theorists refer to orderings of social states; that is, alternative complete descriptions of the world. Similarly, the nature of the individual orderings is not specified by the theorem, but social choice theorists refer to individual preferences. On this standard interpretation, the theorem concerns the possibility of aggregating a set of individual preference orderings over states of the world into a single social ordering.

Arrow (1951) investigated four conditions that impose requirements on the process of aggregation. Condition U, the condition of unrestricted domain, requires the process of aggregation to operate for arbitrary sets of individual orderings. Condition P, the weak Pareto principle, requires that if every individual ranks α above β, then society must rank α above β. Condition I, the independence of irrelevant alternatives, requires that the social ordering over any pair of alternatives depends only on individual orderings over that pair of alternatives. Condition D, nondictatorship, requires that there be no individual whose ordering becomes the social ordering regardless of the orderings of all other individuals. The four conditions were viewed by Arrow as necessary but insufficient conditions for rational social choice. The theorem is that there exists no process of aggregation which satisfies all four conditions.

Much of normative economics is welfarist in the sense that it takes individual utilities to be the only admissible information, and Paretian in the sense of Arrow's condition P. In fact welfarism can be thought of as the combination of Arrow's conditions U, P, and I; so the Arrow theorem can be seen as demonstrating the impossibility of nondictatorial welfarism.

A second impossibility theorem highlights the tension between the weak Pareto condition and a weak concept of individual rights. The relevant concept of a right is that an individual is decisive in the choice between a particular pair of alternative social states - a pair that might differ only in some respect deemed to be private to that individual - so that individual A has a right with respect to social states α and β if and only if A's ranking of α and β is causally sufficient to determine the social ranking of α and β.

Sen (1970a) shows the impossibility of a Paretian liberal by proving that no social choice rule can simultaneously satisfy the weak Pareto condition and grant at least two individuals rights over (distinct) pairs of alternatives.

2 Interpretation and critique

Sen (1977) offers four settings in which the Arrow result may be considered: (1) the aggregation of individual interests into overall ethical judgments of social welfare, (2) the aggregation of individual ethical judgments into overall ethical judgments of social welfare, (3) the aggregation of individual interests into social decisions, (4) the

aggregation of individual ethical judgments into social decisions. Settings (1) and (2) cast social choice theory in terms of ethics, while settings (3) and (4) cast social choice theory in terms of politics. Alternatively, settings (1) and (3) focus on the aggregation of private interests or utilities, while settings (2) and (4) focus on the aggregation of broader judgments of overall value. While the theorem applies equally in each of these settings, its interpretation and significance varies.

The now standard interpretation of the theorem in setting (1) is that simple personal preference orderings cannot in themselves provide sufficient information to ground social evaluations. Further information may take either of two forms; it might be more detailed information concerning the welfare of individuals, or it might relate to non-welfare aspects of individuals. Within the confines of welfarism, the two most obvious types of further information arise from the cardinality of individual utility and the interpersonal comparability of utility. In fact, if cardinality is allowed, but incomparability maintained, the Arrow result is not seriously affected. But once interpersonal comparability is allowed, the nature of the feasible social orderings depends upon the measurability of utility and the extent of interpersonal comparability. Thus, if ordinalism is retained alongside full comparability, social orderings such as that generated by the maximin criterion are feasible. Of particular interest is the simple utilitarian ordering in which social states are ranked by reference to the simple sum of individual utilities. Such utilitarianism requires at least cardinal scale measurability and at least unit comparability.

If welfarism is breached, so that further categories of information are allowed, the feasibility of social orderings depends on the answers to similar questions concerning the measurability of the new aspect of wellbeing, and its commensurability both across individuals and with utility.

In setting (2) we move from individual utility to individual judgments of social welfare, and it is here that the Arrow theorem is most persuasive. There can be no appeal to additional information in this case, since individual judgments may be taken to be all-things-considered judgments. However, the novelty and practical significance of the theorem may be relatively slight in this setting. It is hardly a surprise to find that different value systems (individuals' judgments of social welfare) are, in general, incompatible with each other.

In settings (3) and (4) we move from ethics to politics in viewing social decision-making rules based on individual interests or individual ethical judgments; we are concerned with the more practical matters of the design of voting systems or committee procedures. One general point to be made is that in these settings we are often not concerned with generating a full social ordering over the alternatives, but with selecting a winner (or set of joint winners). This fact allows us to weaken the requirements placed on the aggregation process slightly and so formally escape from the impossibility theorem. But this escape is more apparent than real. If we require the choices made by our voting rule to satisfy even rather weak consistency conditions, new impossibility results arise.

In these settings the Arrow theorem extends and generalizes the results on specific voting mechanisms associated with Condorcet and Borda, most famously that simple majority voting over at least three alternatives can yield intransitivities or cycles - so that even if all voters have well-behaved preferences over the alternatives, and each votes in accordance with those preferences, alternative α can be majority-preferred to alternative β, alternative β majority-preferred to alternative γ, and alternative γ majority-preferred to alternative α. A further result which follows from the Arrow theorem when interpreted in terms of social decision making relates to the manipulability of voting mechanisms. Broadly, the result is that all feasible voting schemes will, in general, provide incentives for individuals to vote strategically; that is, to misrepresent their true preferences in an attempt to manipulate the outcome of the vote.

The debate on the impossibility of a Paretian liberal has been voluminous. Topics considered include a variety of conceptions of individual rights - the contrast between the right to determine an aspect of a social outcome and the right to determine the individual's own strategic behaviour, for example; the extent to which preferences might be laundered to exclude the meddlesome preferences of one individual over matters deemed to be private to another individual; the extent to which the ability to trade rights might eliminate the results, and so on. Whatever the modifications to Sen's original structure, it seems that if aspects of individuals other than their preferences or values are to be included in the process of social evaluation or decision making, further conflicts await.

A fundamental criticism of the basic enterprise of social choice theory first put by Buchanan (1954) argues from an individualistic perspective that it is simply inappropriate to investigate social evaluation or social decision making

against criteria of collective rationality. This approach suggests that while individuals may be able to articulate evaluative orderings over alternative states of the world, there is no sense in the idea of a social or aggregate evaluative ordering. Furthermore, if collective decision making rather than evaluation is the focus of attention, we must attend to the question of how individuals might agree on decision-making procedures. In a commonly used example, we might agree to a process of simple majority voting in certain contexts without any commitment to the idea that the outcome of this political procedure is in any aggregate sense best. The claim is that the appropriate framework for the study of collective action problems is provided by the model of voluntary exchange between individuals. This position is strongly linked to a generally contractarian view of both politics and ethics (see Contractarianism).

3 Economics and ethics

Social choice theory has stimulated considerable work in the intersection of economics and ethics. In part this is because of the detailed, formal attention paid to questions such as the measurability and comparability of welfare, or the specification of individual rights; in part because of the implications of the theory for the classic debates between consequentialist and non-consequentialist moralities, or between liberalism, utilitarianism and contractarianism; and in part because of the illumination of the relationships between rationality and morality. It is not too difficult to justify the claim that social choice theory has had a major impact on both normative economics and moral theory - but most especially on the interaction between the two.

The debate in normative theory is in sharp contrast to the earlier orthodoxy within economics, when economics was seen as a predominantly technical study divorced from value judgments. Traditional neoclassical economics of the type captured in the textbooks of the mid twentieth century might be caricatured as depending on the twin ideas of a simple conception of self-interested, utility-maximizing individual rationality and an equally simple welfarist conception of the public interest. Initially social choice theory challenged the assumed link between these two ideas, but much of the continuing contribution of social choice theory lies in the more detailed re-examination of each idea. In the same way, while many of the relatively early contributions to social choice theory might be seen as technical exercises in aggregation theory, the more lasting contributions are those which engage with the substantive issues in ethics or political philosophy. In this way social choice theory has provided the basis for contributions which draw on the technical apparatus of economics in addressing topics of perennial interest to philosophers, while at the same time opening up the possibility of a reverse flow of ideas from philosophy into economics.

Social democracy

The idea of social democracy is now used to describe a society the economy of which is predominantly capitalist, but where the state acts to regulate the economy in the general interest, provides welfare services outside of it and attempts to alter the distribution of income and wealth in the name of social justice. Originally 'social democracy' was more or less equivalent to 'socialism'. But since the mid-twentieth century, those who think of themselves as social democrats have come to believe that the old opposition between capitalism and socialism is outmoded; many of the values upheld by earlier socialists can be promoted by reforming capitalism rather than abolishing it.

Although it bases itself on values like democracy and social justice, social democracy cannot really be described as a political philosophy: there is no systematic statement or great text that can be pointed to as a definitive account of social democratic ideals. In practical politics, however, social democratic ideas have been very influential, guiding the policies of most Western states in the post-war world.

1 Social democracy *c*.1880-1940

In its earliest phase, social democracy became the leading form of socialism in Western societies (see Socialism). It emerged from a fusion between the ideas of revisionist Marxists such as Eduard Bernstein and those of 'new' liberals such as L.T. Hobhouse who had come to believe that some form of socialism was necessary in order to realize liberal ideals. It differed from the Marxism promulgated by Lenin and his followers in the international communist movement in three main respects. First, in place of the belief that the economic collapse of capitalism was inevitable, the social democrats held that capitalism could only be transformed by the political will of the people; it was important, therefore, to emphasize not only class struggle, but the aims and ideals of socialism. Second, the transformation would not occur in a single revolutionary moment but over an extended period of time, with changes in economic structure being guided by social democratic parties holding political power. Third, the social democrats accepted the procedures and constraints of parliamentary democracy: confident that they could, in due course, win majority support, they saw the route to power lying through open elections.

In this phase, therefore, the final aim of social democracy was to replace private ownership of industry with state or social ownership, but the means were to be those of parliamentary democracy.

2 Social democracy *c*.1940-

In the second, mainly post-war, phase, social democrats came to believe that their ideals and values could be achieved by reforming capitalism rather than abolishing it. They favoured a mixed economy in which most industries would be privately owned, with only a small number of utilities and other essential services in public ownership. Their reformism expressed itself in four main directions.

(1) Under the influence of Keynes, they believed that, by controlling the level of public expenditure, the state could also control the level of aggregate demand, thereby preventing the expansion-recession cycles of uncontrolled capitalism (see Keynes, J.M. §2). In this way, steady economic growth and full employment were achievable.
(2) The state should provide welfare services (health, education and so forth) free of charge to all who needed them, and should also create a social insurance scheme for those temporarily unable to find work. Together these initiatives would create a social minimum that every citizen would be guaranteed regardless of personal circumstances.
(3) Workers' rights should be protected by legislation and the formation of trade unions, and the state should encourage workers' participation in the management of firms through co-determination schemes and the like. There should be (some degree of) economic democracy alongside democracy in the state itself.
(4) The first three measures would together serve to create considerably more social equality than was possible under unreformed capitalism. But, in addition, the state could legitimately use its powers of taxation and public provision to correct the distribution of resources still further, for instance by taxing incomes at progressive rates and using the proceeds to provide subsidies for the poor (such as cheap housing).

Social democrats argued that in these circumstances the old debate about the ownership of industry had become an irrelevance. Properly controlled, capitalism could be relied upon to produce the resources that social democratic governments could then use to advance their ideals practically. These ideals were a widening of democracy beyond the state to encompass economic and social organizations; social justice, in the sense of equal opportunity to achieve positions of advantage, together with the guaranteed social minimum as outlined above; and, less tangibly, a greater sense of community among citizens to offset the atomizing effects of the market economy.

In the last quarter of the twentieth century, the most powerful challenge to these ideals has come not from socialists but from libertarians, who argue that regulation of the market and redistribution of its proceeds are not only morally illegitimate but also likely to be self-defeating (see Libertarianism). Their cause has been aided by increasingly intense international economic competition, which has narrowed the range of policy options open to social democratic governments. Yet the ideals of social democracy have retained their popularity, and much recent political philosophy can be seen as an attempt to formalize and ground these ideals (see Dworkin, R.; Rawls, J. §4).

Social epistemology

Social epistemology is the conceptual and normative study of the relevance to knowledge of social relations, interests and institutions. It is thus to be distinguished from the sociology of knowledge, which is an empirical study of the contingent social conditions or causes of what is commonly taken to be knowledge. Social epistemology revolves around the question of whether knowledge is to be understood individualistically or socially.

Epistemology has traditionally ascribed a secondary status to beliefs indebted to social relations - to testimony, expert authority, consensus, common sense and received wisdom. Such beliefs could attain the status of knowledge, if at all, only by being based on first-hand knowledge - that is, knowledge justified by the experience or reason of the individual knower.

Since the work of the common sense Scottish philosopher Thomas Reid in the mid-eighteenth century, epistemologists have from time to time taken seriously the idea that beliefs indebted to social relations have a primary and not merely secondary epistemic status. The bulk of work in social epistemology has, however, been done since Thomas Kuhn depicted scientific revolutions as involving social changes in science. Work on the subject since 1980 has been inspired by the 'strong programme' in the sociology of science, by feminist epistemology and by the naturalistic epistemology of W.V. Quine. These influences have inspired epistemologists to rethink the role of social relations - especially testimony - in knowledge. The subject that has emerged may be divided into three branches: the place of social factors in the knowledge possessed by individuals; the organization of individuals' cognitive labour; and the nature of collective knowledge, including common sense, consensus and common, group, communal and impersonal knowledge.

1 Reliance on testimony

The epistemological status of testimony and received wisdom is the topic in social epistemology which is most extensively treated in classical texts and contemporary discussion, and the only topic for which we have a detailed history (Coady 1991) (see Testimony). The central question here is whether testimony is a source of individual knowledge not derived from a non-social source like perception. According to *strong* individualism, to whichJohn Locke subscribes, all knowledge must be first-hand; no belief can be epistemically justified on the basis of testimony (where epistemic justification is the kind of justification required for knowledge - see Justification, epistemic §1). The objection to this view is that it entails a broad scepticism, excluding my knowledge of such matters as my own date of birth and the proposition that a cloudless sky is usually blue. According to *weak* individualism, a belief may be justified on the basis of testimony, but any such belief must ultimately be justified on the basis of non-testimonially justified beliefs. There are at least three versions of weak individualism:

(1) On the *inductive* version, to which David Hume subscribes, a belief based on testimony (call it a 'testimonial belief') is justified on the basis of the non-testimonially justified belief that the testimony is trustworthy or reliable (that is, tends to be true), which in turn is justified by induction from non-testimonially justified beliefs (see Testimony §3). The most significant objection to the inductive version is that we rely on testimony for many of the beliefs that would have to serve as the non-testimonial basis of the induction to the reliability of testimony. It is practically impossible to check at first-hand more than a tiny fraction of the reports given by testimony. Hence, the basis for an induction is too slim to justify the belief in reliability.
(2) On the a priori version of weak individualism, a testimonial belief is justified by appeal to an epistemic parity between my own beliefs and those of others. The idea that one person is epistemically no better than another is ancient and was assumed by Sextus Empiricus in the following maxim, which he used to argue for Pyrrhonian scepticism: where others disagree with me, I ought to suspend judgment. The present appeal to parity reverses the sceptical strategy of Sextus. A priori, I have no more reason to trust my own beliefs than I do those of others. Consequently, if I may trust my own beliefs, I may also trust others' beliefs, and thus I am justified in my testimonial beliefs. An objection to this version is that it equivocates on 'trust'. Perhaps I must trust others in the same sense in which I must trust myself. But why suppose that it follows that others' beliefs are trustworthy or reliable in a sense relevant to *my* being justified in having the same beliefs, rather than in a sense relevant to *their* being justified in these beliefs? There is no reason a priori to suppose that my epistemic position is similar to theirs in a way that makes these beliefs justified for me as they are for them. Thus it does not follow that my testimonial

beliefs are justified.

(3) On the coherence version, a testimonial belief is justified by its coherence with non-testimonially justified beliefs. The trouble with this proposal is that the objection to the inductive version shows that there is very little coherence between any given testimonial belief and the non-testimonially justified beliefs that might form the basis of an induction to the reliability of the testimony. No doubt testimonial beliefs are often unsurprising and in this sense fit with non-testimonial beliefs. But the epistemic force of this lack of surprise depends on antecedent generalizations about the world, and these in turn depend on prior testimony. Nor can the proponent of the coherence version retreat to the idea that testimonial beliefs are justified by the coherence of all beliefs together, testimonial as well as non-testimonial. For this is no longer a version of weak individualism, since testimonial beliefs are no longer justified on the basis of non-testimonially justified beliefs alone. True, it still counts as a version of individualism. But since we currently have no idea how all these beliefs are supposed to cohere, it seems we lack an individualist account of the justification of testimonial beliefs.

What is the alternative to individualism? Reid proposed that we take the justification of testimonial beliefs to be underived, on a par with the justification of perceptual beliefs (see Reid, T. §7). The justification of testimonial beliefs is governed by a first (that is, underived) principle, ‘That there is a certain regard due to human testimony in matters of fact, and even to human authority in matters of opinion’ (Reid [1785] 1969: 640). Conformity to this principle is made possible by certain innate dispositions of the human constitution: the principle of veracity, which disposes us to tell the truth, and the principle of credulity, which disposes us to believe what is said. First principles are not susceptible to proof, though they can be supported by recognizing their similarity to other first principles, under various desiderata, including common assent, conformity to the human constitution and practical necessity. In the terms of subsequent epistemology, Reid appears to have proposed that testimonial beliefs are *prima facie* justified in a manner analogous to the *prima facie* justification of perceptual beliefs. They are, at least early on, basically (that is, non-inferentially) justified and can be defeated by the subject’s other testimonial and non-testimonial beliefs.

2 Conditions of knowledge

Reid incorporates social factors into the conditions of justification by adding a principle of testimony. Others have proposed that the conditions of knowledge are in some sense social throughout. In particular, the content of the concept of knowledge is inherited from the social function of the concept of knowledge. Not all social functions of a concept are manifested in the content of the concept, but if the concept of knowledge has what we might call a social *epistemic* function, then perhaps it also has a social content. There are several examples of this approach.

Edward Craig (1990) has argued that the concept of knowledge is used in testimony as a tag to identify good informants. The concept of knowledge is not identified with the notion of a good informant itself, since knowing does not require being able to communicate to others the proposition believed, as does being a good informant. Rather, the proposal is that the concept of knowledge is an ‘objectivization’ of the notion of a good informant - a concept in which some of the features of a good informant that serve specific uses are stripped away. An analogous idea is that the concept of justification is used to identify *justifiers* - people able to justify a claim to an audience. On the most straightforward version of this view, suggested by David Annis (1978), one is justified in a belief (or claim) (relative to an audience) just in case one is able to justify it to the audience - or at least to hold one’s own in a conversation in which the claim is challenged. With regard to all such approaches, one worries that they have singled out a particular use of the concept of knowledge at the expense of other uses, uses that demand a different conceptual content (see Justification, epistemic §7).

3 The organization of cognitive labour

Traditional epistemology has little to say on the matter of how individuals should coordinate and institutionalize their inquiry to enhance their prospects of obtaining individual or group knowledge. In recent years, epistemologists have taken an interest in this matter, especially as it applies to science. One question concerns the obligations of individuals to disseminate information to or withhold it from others. A.I. Goldman (1992) has argued for *epistemic paternalism*, the view that individuals should sometimes withhold information to enhance the prospects that recipients will arrive at knowledge or true belief - as, for example, when evidence of a crime is ruled inadmissible in a court of law to prevent the jury from being misled. A second question is what features

interpersonal argumentation should have if it is to serve the development of knowledge. A third question is whether, to enhance the prospects of scientific group knowledge, individuals (or subgroups) should pursue lines of inquiry that are unpromising or based on improbable theories. A fourth question is whether individuals' cognitive biases induced by their social interests, such as ambition for professional credit, may steer individual research and belief-formation in such a way as to enhance the prospects of proper group belief-formation.

4 Collective knowledge

The key question of collective knowledge - of common, group and communal knowledge - is whether it reduces to individual knowledge or amounts to something over and above individual knowledge. A related question is whether individual knowledge must in some way be assimilated to communal knowledge (that is, the knowledge possessed by a community). The pragmatist C.S. Peirce argued for an affirmative answer to the latter question on the ground that the aim of proper method must be understood socially (see Peirce, C.S. §2). Peirce (1955) took the aim of proper method not to be true belief but relief from doubt. He then argued that the aim must be common rather than individual relief from doubt, since the 'social impulse' will drive people to think that others' opinions are as good as their own, and thus differences of opinion will induce doubt. One might question whether it follows from the claim that relief from doubt depends psychologically on common relief from doubt, that the aim of proper method is common relief from doubt. But Peirce could reply that there is no point in taking relief from individual doubt as the aim when we will in any case have to aim at common belief. Clearly, Peirce's argument for a common aim of proper method carries more weight for beliefs that are publicized, as in the case of science, than for beliefs that tend not to be exposed to the doubts of others (for example, beliefs about the details of one's private life).

It is natural to think that Peirce's argument, if successful, undermines a sharp distinction between individual and common knowledge, since a lone individual evidently cannot employ a method that aims at common beliefs; the coordinated efforts of many individuals are required. But whether Peirce's argument goes this far depends on what a proper method involves. If it involves only accumulating the evidence that would suffice to dispel doubt, rather than including the social actions that actually dispel doubt, then an individual on their own may still employ a proper method.

There are other accounts of individual justification that in some way assimilate it to communal justification. In *On Certainty*, Wittgenstein suggests that an individual's belief is justified by appeal to certain communally accepted claims. On a multi-perspectival view of justification, an individual is justified in believing *p* only if *p* is accepted from each perspective represented in the individual's community. Another view is that a belief is justified only if it conforms to communally accepted rules (see Contextualism, epistemological).

Even if individual knowledge is not assimilated to communal knowledge, there remains the question of whether common or group knowledge stands over and above individual knowledge or, instead, reduces to it. *Common* or *mutual* knowledge does reduce to individual knowledge: it obtains when two or more individuals know a proposition, know that each of the others knows, and so on. Common knowledge has proved an essential ingredient in the analysis of social conventions and group knowledge, but whether it amounts to group knowledge is a matter of controversy.

The simplest individualistic account of group justification is a *summative* account: a group is justified in believing a proposition just in case most (or all) of its members are justified in believing the proposition. Opposed to an individualistic account is a *joint* account, on which group justification is not a matter of group members being justified in believing *p*, but of members jointly possessing a good reason to believe *p*, where members jointly possess a reason for *p* just in case they openly express a willingness to treat it as a reason for *p*. The joint account characterizes group justification in terms of the actions and attitudes of the group members. It thus avoids requiring for group justification that there be some group mind over and above the minds of the members of the group.

5 The social construction of knowledge

There are three senses in which it has been claimed that knowledge is socially constructed (see Constructivism). (1) Some sociologists of science (for example, Bruno Latour 1987) have proposed that the facts reported in scientific journals are fabricated by the manipulation of inscriptions involving 'modalities' (that is, ways of

embedding sentences in other sentences). It has also been proposed (Joseph Rouse 1987) that many scientific laws strictly apply only to artificially created laboratory phenomena and extend to phenomena in nature only by analogy; thus, a law implicitly refers to the social conditions in which laboratory phenomena are created. (2) It has been proposed (again by Rouse) that the conditions of scientific communal knowledge are social. The argument is that the standards of knowledge to which scientific theories and experimental results are held (for example, the degree of confirmation required) depend on the uses to which the theories are put, and these uses are in turn determined by research needs, hence by the social conditions that determine those needs. (3) Finally, it has been claimed, particularly by those associated with the ‘strong programme’ in the sociology of science, that scientific theoretical and observational communal knowledge, or at least beliefs that are esteemed knowledge, are caused by social, economic and political interests. This sociological causal claim contrasts with *rationalism* about the causes of scientific theory choice, according to which theory choices are caused by rational reasoning on the basis of observations and theoretical desiderata, except where noncognitive factors (such as desires, emotions, peer pressure and the like) interfere with rational choices and pre-empt them.

One argument for the sociological causal claim is a priori: theories are underdetermined by observations and so choice is not caused by observations alone but by social interests (see Underdetermination). Nor can rationalists appeal to theoretical desiderata like simplicity and explanatory power to explain theory choice in the face of underdetermination, since these desiderata are merely rationalizations of theory choice, not rationally supported independently of choice. This objection to rationalism underestimates the theory-independent grounds for desiderata like simplicity - such grounds as that simpler theories carry less information than complex theories and thus accepting them entails less exposure to the risk of error (see Theoretical (epistemic) virtues). These grounds for deciding between theories are sometimes said to be theory-laden, leaving the choice of theory once again unexplained. But even if this is so, the way in which these grounds are selected may depend on metaprinciples relating grounds and theories.

Sociologists have also supported the sociological causal claim by appeal to historical case studies of the role of interests in theory choice (see Gender and science §3; Marxist philosophy of science; Postcolonial philosophy of science; Sociology of knowledge). But the poverty of the historical materials makes it difficult to establish that interests cause, and are not merely correlated with, theory choice in these cases. However, a correlation between interests and theory choice, even if not shown to be causal, may be hard to reconcile with rationalism, since we would not expect interests to be correlated with rational choices.

Social laws

Social science has always aspired to be like natural science (Hawthorn 1976). And since natural science claims to discover laws of nature, social science has always claimed to discover laws of society. There are two important problems raised by such social laws. What makes the laws social in the appropriate sense? And if they really obtain, does that mean that human beings are not as autonomous as one might have thought: that we are pawns in a game that the laws control?

We may take laws here in a more or less unanalysed fashion as reliable regularities, usually reliable causal regularities, in the succession of events on one another. The statement of a causal law will postulate that whenever an event of a certain type is realized then an event of another type is also going to be realized, perhaps so close in time that they overlap, perhaps at some temporal distance. Or, more plausibly, it will postulate a probabilistic and bounded version of that sort of linkage. The linkage will be probabilistic to the extent that the first sort of event is held to raise the chance of the second sort occurring, not to make it inevitable. And it will be bounded so far as it is assumed to obtain only under certain boundary conditions: only when other things, usually other unspecified things, are equal.

What are the laws of the social realm that the social science project envisages? They cannot by all accounts be just the sorts of laws that empirical psychology, or the sort of psychology employed in microeconomics, postulates. They cannot just be regularities in the way people's individual beliefs and desires, probabilities and utilities, are formed and develop. They must be distinctively social laws (Brown 1984).

A law will be a distinctively social law, we may presume, just where the properties that it involves are, or at least include, some social properties. But what is it for a property to be social? There are many rival accounts (Ruben 1985). One simple one holds that a property is social just where it cannot be realized unless a number of intentional subjects, usually interactive intentional subjects, hold by certain attitudes or exhibit certain actions. The property of an individual that they are a judge or a celebrity, the property of a place that it is a country or a football field, the property of a group that its members meet on Sundays or that they generally go to sleep before midnight: these are all social properties on this generous account.

There is little doubt but that there are social laws, under this account of social laws (Pettit 1993). It is a putative law, however probabilistic and bounded, that urbanization leads to secularization, that an increase in unemployment leads to a rise in crime, and that commercial firms tend to approach the profit levels of their rivals. Such laws indeed are social in quite a strong sense. While the properties involved cannot be realized without a number of people displaying certain intentional actions or attitudes - that is what makes the properties social - still the laws are not just an extension of the body of psychological laws. They do not introduce factors that might be thought to interact with the variables of established psychological laws, thereby extending the laws causally. Nor do they involve patterns that are logically secured just by the fact that certain psychological laws obtain: they are logically as well as causally discontinuous with psychological laws.

Do social laws, so understood, threaten the sense that we human beings have of ourselves as relatively autonomous thinkers and agents? Those who espouse a collectivist or structuralist vision of social science, for example many in the tradition of Durkheim, tend to say that they do; they tend to take social science, in particular the discovery of social-structural laws, as a challenge to our ordinary common-sense view of ourselves. The idea is that whereas common sense represents us as forming attitudes and actions in response to familiar, more or less rational pressures, social science reveals that we are destined, perhaps even determined, to behave in the manner that certain aggregate social laws require. We are the unknowing dupes of those impersonal dictators (see Structuralism in social science §1).

But this vision of dictatorship by social law - this version of the 'death of the subject' - is uncompelling. It is more plausible to think of social laws as related to intentional or psychological laws - the laws that ensure our relative autonomy - in an architecture of the following kind (Pettit 1993). A higher-level social law relates an antecedent which is variously realizable at the intentional level to a consequent that is variously realizable at the intentional level: so urbanization or secularization may come about via any of an indeterminate number of actions, and any of

an indeterminate variety of attitudes, on the part of individuals. If the antecedent is related in a law-like way to the consequent, that is because the intentional realizers of the antecedent, no matter what they are, are more or less bound to lead, under the intentional laws, to the realization of the consequent. The realization of the antecedent ‘programmes’ for the realization of the consequent helps to ensure the realization of the consequent in a manner that depends on more or less familiar psychological regularities, not in a manner that imposes an alien order on the intentional realm.

This architecture is attractive, because it would enable us to see how social science may discover surprising laws without undermining our image of ourselves as more or less autonomous agents. It would also enable us to see how such laws can be logically discontinuous from the body of psychological laws. The laws may obtain, not just in virtue of psychological laws, but also in virtue of the boundary conditions under which those laws rule. If unemployment leads to crime, that may be a result, not just of the way human psychology works, but also of contingent features of the world in which it works: in a world where the unemployed could always have recourse to wild fruit and warm beaches, for example, the regularity might well break down.

Social norms

A social norm may be defined as the rule of a particular social group. That men are to open doors for women, for instance, may be the rule of a particular group. But what is it for a group to have a rule, according to our everyday understanding? Philosophers have disagreed on this point. An important general issue is whether a group's having a rule is a matter of some or all of its members individually conforming to the rule or individually accepting the rule as a standard of behaviour for the group. An alternative type of account invokes the idea of the group's members jointly, rather than individually, accepting the rule, in effect agreeing to conform to it. It can be argued that this less individualistic account better explains the way in which people criticize deviations from social norms.

1 Lewis' game-theoretic account of social convention

Lewis (1969), following Schelling (1960), proposed an account of (social) convention such that underlying every convention is a recurring 'coordination problem' that will be solved by members' regular conformity to a certain pattern of behaviour (see Lewis, D.K.). A typical coordination problem occurs when a telephone conversation is cut off. Each party wants the call reconnected. If both call back, however, or if both wait, no reconnection will take place. There is a need for coordination of behaviour in order that the result both prefer occurs.

Lewis' proposal is roughly this: by definition, there is a convention when and only when a suitable regularity in behaviour arises within a coordination problem, accompanied by expectations of conformity. He argues that conventions in his sense are 'norms': we believe that those with such a convention ought to conform to it, since otherwise they go against their own and the other parties' preferences (1969: 97). That may be so, but the question remains whether conventions according to Lewis are social norms in the sense of group rules (see Decision and game theory).

Critics argue that Lewis has not captured the vernacular concept of a social convention, as he hoped (see, for instance, Gilbert 1989, ch. 6). Among other things, conventions do not only arise in the context of coordination problems. Further, it can be argued that from an intuitive point of view social conventions are a class of group rules. According to Lewis' definition, conventions do not amount to group rules intuitively. Among other things, if a convention were a group rule, the parties would understand they had reason to conform irrespective of their personal preferences and expectations.

2 Hart's practice theory of social rules

Hart's account of social or group rules runs roughly as follows: for there to be a social rule, a certain pattern of behaviour must be regularly conformed to within a given group. In addition, members of the group must regard the pattern as a standard by which group members' behaviour may be judged correct or incorrect. They must believe that, all equal, members ought to conform to it. Further, group members must believe they are justified in pressuring one another to conform. In typical cases, such pressure will be imposed on deviants and those who threaten deviance (see Hart, H.L.A.).

These conditions seem not to rule out cases like the following. The individual members of a group believe that lying is wrong. They also believe that members are justified in pressuring one another not to lie. In the situation as described, however, the rule proscribing lying does not seem to be a genuine group rule, as opposed to a rule that everyone individually accepts (and deems it appropriate for everyone to enforce) (Dworkin 1977; Hart[1961] 1994, postscript). What is missing from this case?

As Hart himself observes, when a group has a rule the members take themselves to be justified in the imposition of pressure on others solely because of actual or threatened violation of a rule of their group. This is so whether or not they take the rule to be a moral one. (Presumably the rule that men are to open doors for women might not be perceived as a moral one.) This suggests that an adequate account of social rules will make clear how, by their nature, they justify the imposition of pressure for conformity.

3 Gilbert's joint acceptance account of social rules

If we are looking for something other than a moral rule to ground an entitlement to exert pressure on others, an obvious candidate is something akin to an agreement. If you and I have agreed to act in a certain way in the future, and I then act differently, we will both understand that I have failed in an obligation I had to you, and that you therefore have grounds for reproving me, whether or not you choose to do so.

Of course group members do not in general get together and agree to conform to certain standards. Commitments of the sort involved in an agreement can be set up, however, without an agreement proper being made. Language can play a role here, as when members accept appeals to ‘our’ rule, with the attendant commitments that this may imply (Gilbert 1989, ch. 4).

Gilbert (1989, ch. 6) suggests that a social convention as ordinarily understood is a jointly accepted fiat, while a social rule is a jointly accepted rule, that may or may not be of the fiat form. For members of a population jointly to accept a rule is for them to enter a ‘joint commitment’ to accept that rule together, that is, as a body. A joint commitment is one that is seen by the participants precisely as joint: it is not the sum of the different individual members’ independent commitments. Rather, it is our commitment. All are committed through it, but these ‘individual commitments’ have a single source in the joint commitment, on which they depend. Each member is beholden to the others for release from the commitment. A joint commitment may be said to involve mutual obligations of a particular sort, and to provide grounds for reproof if the commitment is not complied with (Gilbert 1996).

Given this appeal to the notion of a joint commitment (which she sees as a fundamental intuitive concept) Gilbert argues, in effect, for a more holistic, less individualistic account of social norms than is envisaged by Hart or Lewis. Rules jointly accepted by group members are more aptly referred to as the rules of a group than are rules merely conformed to or individually accepted by group members.

Social relativism

People in different societies have very different beliefs and systems of belief. To understand such diversity is a prime task of the student of society. The task is especially pressing when alien beliefs seem obviously mistaken, unreasonable or otherwise peculiar. A popular response is social relativism. Perhaps beliefs which seem mistaken, unreasonable or peculiar viewed from our perspective, are by no means mistaken, unreasonable or peculiar viewed from the perspective of the society in which they occur. Different things are not just thought true (reasonable, natural) in different societies - rather, they are true (reasonable, natural) in different societies. Relativism recognizes diversity and deals with it even-handedly.

Relativism has absurd results. Consider the view that what is true in society A need not be true in society B. So if society A believes in witches while society B does not, there are witches in A but not in B. Relativism regarding truth drives us to different 'worlds', one with witches in it and another without. This seems absurd: people who live in different societies do not in any literal sense live in different worlds. The challenge is to do justice to social diversity without falling into absurdities such as this.

1 Social diversity

Social diversity is one of the first and most familiar facts to strike the student of human beings and the societies in which they live. The foregoing treats of the social diversity of belief. Along with different beliefs come differences in behaviour, customs, rituals, traditions, conventions, institutions, political and legal arrangements, and so forth. For instance, some people enact ritual dances to ensure that rain will fall on the crops, others think that pregnancy has nothing to do with sexual intercourse, yet others blame magical influences for their misfortunes. Here capital punishment is frowned upon, there it is not. Here a particular religion is state-sponsored, there it is not. Many things other than belief-systems are 'relative to' (that is, distinctive of) different societies.

Yet there is good reason to focus on beliefs. The other differences are all constituted by, or sustained by, or at least associated with, differences in belief. Canons of rationality or of value are generally accepted beliefs about what is reasonable or valuable. It is the custom in a society to bury the dead only if sufficiently many members of that society think it is the thing to do and act accordingly. Traditions and institutions are sustained by the beliefs of the participants in them. Actually, there are deep questions regarding exactly how, and to what extent, social phenomena are 'dependent' on beliefs and belief-systems. We cannot enter into those controversies here, but rather focus on the diversity of beliefs, as is customary.

2 Social relativism

An early response to the diversity of beliefs was to distinguish 'primitive societies' (usually African) from advanced ones (usually European). The bizarre beliefs of 'primitive peoples' were just false, the product of irrational, illogical, even 'pre-logical' processes of thought. Then a reaction set in. You cannot really understand a 'primitive' society by viewing it from the perspective of your own and deeming its beliefs and practices false or irrational or pre-rational. Each society should be judged on its own terms. Beliefs deemed false and irrational by our lights may be perfectly sound and rational seen from the perspective of the society which sustains them. Just as belief-systems are socially and culturally bound, so are honorifics like 'true' or 'reasonable' with which they are evaluated. This is social relativism.

Social relativism is not merely the recognition of social diversity or of the difficulty of understanding the arrangements of one society from the perspective of another. Social relativists add that there is nothing to choose between different beliefs and practices. There are no neutral canons of truth or reason which would enable us to do this. Local mistakes remain possible. An incompetent witch-doctor may consult the poison oracle wrongly or have a false belief about the origin of a particular misfortune. An incompetent priest may administer the sacrament wrongly or make a theological mistake. But neither witchcraft nor Christianity can be globally false or irrational. Truth and rationality are themselves relative to societies. No belief or system of belief can be deemed false or irrational *simpliciter*.

3 Proliferation

One worry about social relativism concerns its tendency to proliferate. Societies are pluralistic and ill-defined. One group may enact magical rituals and also spread fertilizers to ensure good crops. Another may keep their cars well-maintained and also bless them with holy water to ensure safe travel. There exists both a Society of Friends and a Society of Accountants. This is no mere pun on the word ‘society’: the beliefs, traditions, practices, and so on, of these two groups are as diverse as one might wish.

Social diversity proliferates horizontally, across different societies at the same time. It also proliferates vertically, down the same (or different) societies at different times. For, as L.P. Hartley said at the beginning of *The Go-Between,* ‘The past is a foreign country - they do things differently there’. Historical diversity is as familiar a fact to the student of history, as social diversity is to the student of society.

One example of historical diversity is particularly important. Some have been tempted to take science and technology as the arbiters of truth and reason, against which all is to be judged. If we want good crops, we know that fertilizing the soil is better than uttering magical incantations over it. We know this because science teaches it. If we have to choose between ‘African traditional thought and western science’, to cite the title of a famous contribution to these debates, by Robin Horton (reprinted in Wilson 1970), it is clear how we should choose. But is ‘western science’ the monolithic system of belief and practice which this seems to suppose? Thomas Kuhn said not. A glance into the history of science reveals the same kind of diversity of belief and practice, as we see today as we look across different societies. Furthermore, Kuhn seemed to say, there is as little to choose between the different ways of practising ‘western science’, as there is between the different beliefs and practices we find today in different societies. Far from being a way out of the relativistic impasse, science viewed historically is a part of it.

One response to social diversity is to maintain that, beneath all the diversity and under-pinning it, there are continuities. All social groups are interested in finding solutions to the basic problems of life, usually detailed as food, shelter and procreation. To that end, all social groups are interested in explaining and, so far as they are able, controlling the phenomena of nature. In pursuit of these basic ends, all social groups have an interest in acquiring beliefs that are true and explanations that work.

Thoroughgoing relativists remain unimpressed. They see diversity even concerning the ‘basic problems of life’. There are peoples who (it seems) believe that pregnancy has nothing to do with sexual intercourse. A common interest in explanation represents continuity only if proffered explanations are of the same type and are adjudicated by common standards. A common interest in true beliefs represents continuity only if there is a common notion of truth.

Like many general sceptical theses, thoroughgoing relativism threatens to self-destruct. ‘All truths are relative to some S’ will itself, if true, only be true relative to some S. One can ask in which S relativism is true. And the best answer seems to involve the society or sub-culture of social anthropologists and their various philosophical hangers-on. Alternatively, one can view relativism as an absolute, ahistorical, trans-cultural truth - in which case, it is false.

4 Idealism

Relativism about truth flies in the face of platitudes. For example, it is true that bloodletting cures diseases if, and only if, bloodletting really does cure diseases. Or generally, something or other is true if, and only if, it is really the case. Such platitudes seem to leave no room for the notion that something might be true for A but not for B. These platitudes assume that what is the case does not in general depend upon what people think is the case. It is to suppose that the world, its objects and their features do not in general depend on our ideas, on our thought or talk. Suppose instead that what is true for one society need not be true for another. It follows that inhabitants of different societies inhabit different worlds. In society A it is believed that diseases are brought about by ill-wishing magicians, in society B it is believed that diseases are brought about by bacteria, viruses and other ‘natural causes’. Some people might think that both beliefs cannot be true (though both might be false). But this is to fall back upon a monolithic, societally-neutral notion of truth. No, it is true in society A that diseases are brought about by ill-wishing magicians - not just thought to be true (that is, believed) but true. It follows that there really are in the world ill-wishing magicians - for inhabitants of society A. Once monolithic truth is jettisoned, so is a monolithic ‘world’ to which monolithic truths ‘correspond’. No, different peoples inhabit different worlds. The world of the

Kalahari bushman is very different from the world of the industrialized European. The world of the Aristotelian scientist is very different from the world of the Newtonian scientist. If truth is socially constructed, so is reality. The world, its objects, and their features depend for their very nature upon what human beings think about the world, its objects, and their features. (And why just human beings? Avoid human chauvinism, and you will have to agree that the world of the chimpanzee or honeybee is worlds apart from the world of Albert Einstein.) This is idealism (see Idealism; Realism and antirealism).

Relativistic and idealistic ways of speaking are popular, and may be innocuous. ‘That’s true for you but not for me’ may just be a picturesque way of saying that you think that true but I do not. ‘Witches really existed in seventeenth-century Europe’ may just be a picturesque way of saying that seventeenth-century Europeans thought that witches really existed. But if we take such locutions literally, they involve us in idealism.

What of logic and rationality - might they be socially relative? Might a people believe that there are witches - and also believe that there are not? Might there be a ‘pre-logical’ society where the logical law of contradiction breaks down? The matter of rationality is more difficult. Beliefs can be rational yet false, and irrational yet true. Our ancestors once believed that the earth was flat - their belief was false, but reasonable given the evidence and argument available to them. Should we now find a society of flat-earthers, we might declare their belief false yet reasonable, for much the same reasons. Alternatively, we might suspect that they do not really believe this and that we have mistranslated utterances which led us to think that they do. The enterprise of translation, however, seems to presuppose that sincere utterances are thought true, and not thought untrue at the same time.

Cultural relativism and idealism are fuelled by a laudable ambition to be even-handed about the beliefs and practices of others. But we can understand the beliefs and practices of others ‘on their own terms’ without dismantling the rational unity of humankind. Indeed, the latter is curiously self-defeating. What is more patronizing than the declaration that this or that is true and real - but just for you? The project is ‘understanding a primitive society’ (to cite the title of another famous contribution to these debates by Peter Winch, reprinted in Wilson 1970). Do you advance that project by claiming that in ‘primitive societies’ understanding means something quite different to what it means in ours?

Social science, contemporary philosophy of

Some philosophers think that the study of social phenomena must apply methods from natural science. Researchers should discover causal regularities (whenever C operates, E occurs) and fit them into systematic theories. Some philosophers hold that social phenomena call for an entirely different approach, in which researchers seek to interpret fully the meaning of people's actions, including their efforts to communicate and cooperate. On this view, the nearest that researchers will come to regularities will be to discover rules (whenever the situation is S, everyone must do A). The nearest that they will get to systematic theories will be systematic expositions of rules, like the rules of a kinship system.

Besides the naturalistic school and the interpretive school, the philosophy of social science harbours a critical school. This finds researches endorsed by the other two schools shot through with bias. It inclines to agree with the interpretive school in resisting naturalistic methods. However, its charges against naturalistic researches extend to interpretations. For interpretations may give untroubled pictures of societies in deep trouble, or picture the trouble in ways that serve the interests of the people who profit from it, for example, by leaving current rules about taking workers on and laying them off unquestioned. Here the critical school may itself use naturalistic methods. If it contends that ignoring ways of reassigning authority over employment increases the chances of private enterprises' retaining their present authority, the critical school is talking about a causal connection. There is no rule that says anyone must increase the chances.

Yet the researches sponsored by the three schools are complementary to the degree that researches into regularities and into rules are complementary. Settled social rules have counterparts in causal regularities, which may be expressed in similar terms, although the evidence for regularities need not include intended conformity. Some regularities are not counterparts of rules, but involve rules notwithstanding. If the proportion of marriages in Arizona ending in divorce is regularly one-third, that is not (as it happens) because one-third of Arizonans who marry must divorce. Yet marriage and divorce are actions that fall under rules.

The three schools do more than endorse studies of rules or regularities. The critical school denies that any study of social phenomena can be value-free, in particular on the point of emancipating people from the oppressions of current society. Either researchers work with the critical school to expose oppression; or they work for the oppressors. The interpretive school brings forward subjective features of human actions and experiences that overflow the study of rules. These features, too, may be reported or ascribed correctly or incorrectly; however, the truth about them may be best expressed in narrative texts more or less elaborate.

Postmodernism has generalized these themes in a sceptical direction. Every text can be read in multiple, often conflicting, ways, so there are always multiple, often conflicting, interpretations of whatever happens. Every interpretation serves a quest for power, whether or not it neatly favours or disfavours an oppressive social class. Such contentions undermine assumptions that the three schools make about seeking truth regarding social phenomena. They do even more to undermine any assumption that the truths found will hold universally.

The assumption about universality, however, is a legacy of the positivist view of natural science. Positivism has given way to the model-theoretic or semantic view that science proceeds by constructing models to compare with real systems. A model - in social science, a model of regularities or one of rules - that fits any real system for a time is a scientific achievement empirically vindicated. Renouncing demands for universality, the philosophy of social science can make a firm stand on issues raised by postmodernism. It can accept from postmodernists the point that scientific success happens in local contexts and only for a time; but resist any further-reaching scepticism.

1 The point of distinguishing schools

Why make anything of a distinction between schools? One could look upon social science as embracing a great number of inquiries on a variety of topics. Some inquiries deal with regularities; some, with rules; some, as much with the one as with the other. They may all be subject to criticism for ignoring other matters, including sometimes their service to current oppressive arrangements.

However, the different contentions of philosophers on the subject of social science demand something like the

three-schools distinction. Among the contentions arise exclusive claims for naturalism; interpretation; critical social theory. The three-schools distinction distributes these exclusive claims under appropriate heads, then confronts them. This is worth doing not only to give the contentions in question due attention. It is in order because social scientists themselves carry on inquiries in different styles answering to the differences between the schools.

The three-schools distinction directs attention to important issues. Is any one school to prevail to the exclusion of the others? If all three survive, because all of them correspond to distinctive and worthwhile inquiries, are the schools and inquiries quite separate? Connections - close and extensive connections - between rules and regularities make the schools allies; and individual inquiries frequently mix the several styles. The schools remain allies, furthermore, when aspects of social phenomena come into the picture that demand philosophical attention though they do not explicitly have to do with rules or regularities.

Chief among these further aspects are, first, the basic subjective features - the temporal structures - of human action and experience, in both of which agents behold the present in a perspective established at once by the immediate past and the foreshadowed immediate future. Second, there is the interpretation of actions as texts the true interpretation of which changes, like the significance of judicial decisions, as history goes on and the perspective of interpretation changes. This is the concern of hermeneutics (see Hermeneutics). Both of these matters can be assigned to the interpretive school, along with a special interest in narratives, without making the school incoherent.

Similarly, the naturalistic school can digest the model-theoretic view of science, without in any way abdicating from advocacy of naturalistic methods (see Model theory). On the contrary, the advocacy becomes more plausible, without encouraging exclusive claims. Within the three-schools framework, the model-theoretic approach, once installed in the naturalistic school, invites application also in the interpretive school. The critical school has for its part a visible opportunity to employ models either of rules or of regularities.

With these new matters accommodated, the relations between the schools need re-examination; and re-examination strengthens the case for complementarity. Moreover, the schools framework furnishes a venue for assessing the impact of postmodernism. How far can it be accommodated, and where? Once the relations within and between the schools have been assessed again, with the lessons about postmodernism allowed for, the relations can be redescribed as relations of inquiries - inquiries concerned with rules, concerned with regularities, concerned with texts, concerned with subjective experience. If one likes, the distinction between the schools, having served all the purposes mentioned, can then be left behind as a historical curiosity.

2 Naturalism recast

John Stuart Mill was a strong early advocate of naturalistic methods in the social sciences; but in the twentieth century its chief advocates were for a long time philosophers grouped at least roughly with logical positivists. During its reign in the philosophy of natural science, positivism held that perfected scientific theories embraced universal laws holding for all times and places. This is an exacting prescription for the natural sciences. In the social sciences it has been impossible to fulfil, and a major embarrassment for the naturalistic school (see Positivism in the social sciences).

The prescription has vanished from the philosophy of natural science with the eclipse of positivism. Yet the revisions that would recast naturalistic doctrines regarding social science to incorporate the now-prevailing model-theoretic view of science have hardly begun. According to this view, as set forth by R.N. Giere (1988), the business of science is accomplished, first, by setting up models with predicates that hold true precisely only of the models and there as a matter of definition; and then showing that the models resemble one range or another of phenomena closely enough to be more useful than other models in prediction and explanation. The predicates may incorporate universally quantified statements (‘In our model of a perfectly competitive market, F’s [rises in price] will always be followed by G’s [increases in supply]’). However, these need hold only for the model or only for the model and (more or less loosely) for some range of phenomena, perhaps just one, strictly circumscribed (markets for pork bellies, given time to raise more pigs). They may also - another important relaxation in scientific standards - go no further in causal content than to specify causal conditions, necessary or sufficient only in the presence of other conditions, and leaving open questions about underlying causal mechanisms. One could know

that the number of pork bellies coming to market in a given year increased only after a rise in prices for pork bellies in some earlier year, without having worked out how one thing led to the other or how quickly.

At one stroke, the model-theoretic approach relieves social science of the burden of finding regularities that hold for all societies. There may be such regularities; in spite of many disappointments it may be worth looking for them; but social science is already working in perfect keeping with the current conception of natural science whenever it works out a model that fits the regularities of just one society, for example, one with money and an organized national market for agricultural commodities. (Indeed, social science does not even have to produce models to work in keeping with scientific standards: it does so just by identifying rules or regularities not identified before, or even just by deploying statistical skills to establish whether the rates of crime or of unemployment are changing.)

Models may originate in attempts, given a mass of information about various societies or various social practices, to draw a simple picture of what those cases have in common. They may be produced with a direct aim of giving a simplified or idealized account of one real case, for example, the economy of Ireland in the late nineteenth century. But then the perspective in which the model is treated is the same as if it condensed a variety of cases. It is carried from one range of phenomena to another to see where it fits.

When statements that would otherwise be taken to be statements by a theory about the world become statements describing a model, it is no longer worrisome whether they are strictly speaking true. We make them true by definition, by postulating a model that answers to the description; and we can make the model as abstract and idealized as we like. If science is in the business of producing models, then it can easily be accepted that the models will often be idealized and will not quite fit any real phenomena. It suffices for a model to come quite close, as it may do in the social sciences as well as in the natural ones, to fitting the phenomena that we want to predict and explain. We do not have to leave the meaning of being close unduly vague. We can count a model as having been improved on when we advance to making more precise predictions of the variables that specially interest us.

The model-theoretic view is also called the semantic conception because the relation of statements describing models to the models is a matter of semantics (while positivism, preoccupied with universally quantified forms of statements, inclined to emphasize the syntax of theories). Models are non-linguistic, even when they are defined in language (maybe mathematical language), without constructing anything tangible to embody the definition. A tangible model can often be furnished if it is demanded. When it is not furnished, diagrams can serve as one-dimensional or two-dimensional physical models. However, models are sometimes clearly not physical at all; logicians use the integers or the positive numbers as models. In any case, models actually produced would belong with items that language refers to rather than with items of language, just as toy trucks or table-top maps would belong with sharks and trees, not with the words ‘toy truck’, ‘map’, ‘shark’, ‘tree’.

An important philosophical issue on which different positions have arisen in the naturalistic school turns on whether all the findings of social science about groups can be reduced to findings about individual persons. Mill held that they can; chief to say that they cannot was the French philosopher and sociologist Émile Durkheim (§2), who contended strongly for a social science oriented to the discovery on the social level of facts that constrained people’s actions and did not simply combine them. Important as this issue is, it does not compel us to divide the naturalistic school into two. Division on the issue is entirely compatible with the pursuit of causal regularities, though on one view these will be (always) reducible to findings about individual persons and on the other (sometimes) irreducibly regularities about groups.

3 The several concerns of the interpretive school

Giambattista Vico (§§4-6), the pioneer of the interpretive school, held that human beings should have every confidence in their ability to understand social phenomena, because the phenomena are all of their own making. ‘Understand’ can be taken here in the broad sense in which we understand celestial phenomena better when we grasp what the red shift implies about the movement of the stars. However, it can also be taken in the sense in which we understand another person’s actions when we appreciate the hopes and fears that led to them. Max Weber (§3), highlighting ‘understanding’ of this sort (*Verstehen*), thought it went hand in hand with explanation. Indeed, any sort of understanding would, though some champions of interpretation, drastically shrinking the scope

of the term, use ‘explanation’ only for attempts at explanation in the naturalistic school.

The study of rules, which are surely of human making, invites Vico’s confidence as much as other concerns of the champions of interpretation. Widely practised, it is continually reinvigorated by new techniques like game theory and by recurrent demands for treating the state and other institutions as systems of rules (March and Olsen 1989; Ostrom 1990). It may serve as a distinguishing mark of the interpretive school. Concern with the study of rules, however, does not do much to identify the other concerns agitating the school, which in its eyes may be much more profound matters.

One such matter, which has found philosophical expression in Edmund Husserl and Martin Heidegger and their followers, is concern that the basic subjective features of human experience receive attention and respect. What does an action mean to the person doing it? This is not a question that is to be answered just by referring to the rules under which the action falls. Simple actions have subjective meanings for the people doing them, consisting of temporal structures in which their awareness of what they are doing shifts from one aspect of it to another (Carr 1986). What agents are aware of as just having done in starting up the action (moving to the door when the doorbell rings) gives way to what they are aware of doing now (turning the doorknob and swinging the door open) and this in turn to what they will be aware of having done when they finish (welcoming the person who has come to the door). Even simpler temporal structures may be embedded in these; they in turn are embedded in more elaborate ones.

A structure does not have to be very elaborate to take on aspects of a narrative. Agents may tell themselves a story as they enact it about how they started, how far they have gone, and towards what outcomes they are headed. (I left a sister behind in East Germany twenty years ago; it is she, I believe, who has just rung the doorbell; if all goes well in the reunion I shall take her into my household.) No references to rules may appear in the telling. The stories may have engrossing meaning for the agents without being for them a story about rules at all.

Narratives are examples of texts. Complex events and actions become texts themselves when the notion of texts is extended in a way that hermeneutics encourages. What do texts mean, judiciously interpreted? This is again a question that does not prima facie make references to rules prominent. It would seem, certainly at first sight, to have much more to do with exploring the larger narratives surrounding a text. (The sister’s coming is a story that fits in a number of intercrossing ways into other stories - family histories; the recent history of Germany; the history of the Cold War.) Hermeneutics as Hans-Georg Gadamer (§3) conceives it is concerned with interpreting texts under a ‘fusion of horizons’. When the texts are actions, only as much place goes to what the actions meant to the agents from what they could see at the time of doing them (with the narratives going on then) as is consistent with giving due weight also to the interpreters’ own horizon of meaning (and the narratives now current). That horizon embraces not only what has happened since the action was done, but also present expectations regarding its further consequences.

A clear example is an opinion delivered by the US Supreme Court, in *Planned Parenthood of Southeastern Pennsylvania* v. *Casey* (1991), a case on abortion. In that opinion Justice Sandra O’Connor held that whatever stand one might have taken at the time that *Roe* v. *Wade* (1973), the crucial previous case, was decided, one must recognize that millions of US women had been assuming for some twenty years that abortion was their legal right. This made a crucial difference now both to the issue and to how the previous case was to be understood.

Concern with the study of rules can be made more congenial to the other concerns at stake in interpretation by fully expressing the complexity of the concern. The interpretive school will be interested (since this is essential to discovering which rules are socially settled ones) in rules that elicit observable conformity. But social scientists who fall in with the school are not to be thought preoccupied with conformity. They are as much interested in the abuse of rules, and in violations. They are interested in rules half-formed and merely advisory precepts. Not least in importance, they are interested in the variable space that a structure of settled social rules may leave for spontaneous, inventive, and innovative action. (Professors have been lecturing in academic gowns; but some begin coming to class in sweaters and blue jeans; they get away with it.) Thus the interpretive school endorses, not so much questions about ‘What rules do given actions fall under?’, but rather ‘In what ways are social phenomena related to the presence or absence of rules?’. That allows considerable room for satisfying other interpretive concerns in the very course of studying rules. Subjective experience and narratives at all levels of generality reflect the impact of current rules, sometimes to a point of saturation or obsession, sometimes to a point of outrage and

defiance.

It is important philosophically to make the point that if social science disregards the subjective forms of experience utterly (as naturalistic inquiries often do), or disregards any of the ways in which their content escapes the study of rules, social science is bound to give an impoverished picture of human life. Yet it would not follow from this that social science could make anything of the subjective forms of experience. Social science seeks generalizations, whether they are generalizations identifying rules or generalizations identifying regularities. For a closer, more exciting approach to the subjective forms of experience people might have to go to biography, fiction, drama, poetry.

In fact social science can make something of the subjective forms of experience. Naturalistic social science conducts surveys, sometimes more penetrating in conception, sometimes less, of people’s feelings. Are people confident enough about holding their jobs to feel satisfied with the government? Confident enough to buy consumer durables? Matters like these are not mere matters of curiosity. Generalized predictions of decline or recovery in the economy may be founded upon them; and incorporating some of them in the models that political scientists have developed for explaining election results may be indispensable. Models taking into account only ‘objective’ variables like income, the rate of unemployment, housing starts, and so on, may not work.

Naturalistic social science working hand in hand with interpretive social science has something to gain from investigating narratives. Narratives shared by whole communities figure in explanations of how the respective communities are formed and maintained. It is already itself a generalization of social science that communities cannot be formed or maintained without such narratives. This generalization, moreover, opens up a branch of inquiry into comparisons of narratives. What sorts of narratives are effective with what sorts of peoples and in what sorts of contexts? If the Japanese had other equally strong sources of community feeling, they might be readier to accept the hypothesis that their imperial family was Korean in origin. Effective narratives might share certain plot-elements across cultures (like Claude Lévi-Strauss’ myth-forms, of which descent of the emperors from a divinity - the Sun-Goddess, in the Japanese case - may be an instance) (see Lévi-Strauss, C. §§5-6).

4 Critical social theory: effective with or without reduction

Does asserting that critical social theory ask naturalistic questions about regularities and interpretive questions about rules imply a ‘reduction’ of it to a combination of naturalistic and interpretive views? The term ‘reduction’ has unwanted overtones. Nevertheless, even in the strong form of saying that in its methods critical social theory is either naturalistic or interpretive, the assertion is strictly compatible with honour for other characteristic features of critical social theory. Distinctive questions, pursued with a distinctive commitment to emancipation, do not imply distinctive sorts of questions or distinctive sorts of methods.

A systematic enumeration of the components of critical social theory would include: (1) distinctive questions, for example, about ideological bias; (2) the thesis that there is no attempt at social science without commitments to political values; (3) commitment, inherited from Karl Marx (§12), to the project of social emancipation; (4) distinctive critical findings respecting both current social arrangements and the limitations of conventional social science. The components may include (5) the thesis that the very phenomena (objects) that critical social theory conceives to be suitable for study in the social sciences differ from those that conventional social science purports to study, and this thesis might extend to implying that the standards of inquiry must differ, too. Further possible components, like an abstract philosophical argument for presupposing a certain ideal of communication (the ideal speech-situation (see Habermas, J.)) as a condition of productive discourse, can be disregarded for present purposes.

Whether much remains of (5), the thesis about studying distinctive phenomena, when due allowance has been made for the other components, and for the full operation of interpretive concerns in social science, is doubtful. For these things do bring in the subjective forms of experience; and value-commitments, displayed in the simplest actions, which are done to reach goals that the agents value. Thus, if critical social scientists wish to say that social phenomena at every level are loaded with value-commitments (which naturalistic social science sometimes ignores), this point is accommodated once interpretive social science gets its place alongside social science with a naturalistic cast.

Suppose, however, this reflection is not enough to convince the proponents of critical social theory that social

phenomena as they view them are treated adequately by the combination of the inquiries that the other schools have in view. (The combination might not be sufficiently intimate or harmonious.) We could have a robust critique of current society and current social science resting on the first four components of critical social theory alone. Call this ‘para-critical social theory’. If it would accomplish substantially the same things in practical political criticism and policy guidance, how much importance attaches to the thesis about distinctive objects?

Some critical social theorists, at some stages of their thinking, would not temporize with social science done under other auspices. They would invoke the thesis of ubiquitous commitment to political values (2); and add that much of current social science is committed not to emancipation but to oppression. Social science that is not committed to emancipation should be eliminated, by vigorously criticizing it, by setting new examples, by supersession. But para-critical social theory could do this work, too.

True, even if peaceful supersession is all that is in prospect, elimination would not be cheerfully accepted in every quarter. A lot of researchers dissent from the position that a thorough-going social transformation is desirable; or favour social transformations that are not (like the project of emancipation) socialist in inspiration. Moreover, a reasonable critical social theorist would concede that criticisms from these quarters of policies at first sight attractive to socialists and emancipators sometimes make useful points, for example, in advancing market solutions to resist unnecessary expansions of bureaucracy.

The demand for elimination is excessive in other ways. The thesis about inevitable commitment to political values is an indispensable argument for elimination. This thesis, however, cannot be put through unless omitting to invoke certain values counts as favour for values opposed to them. Grant this; otherwise there are too many examples of studies or findings that do not mention the values on one side or another, much less explicitly endorse them. It does not follow that the findings coming forward with these omissions deserve no respect. One can think party competition under a capitalist regime no better than a masquerade. Findings about the effects on party competition of single-member district representation as against various schemes for proportional representation advance knowledge notwithstanding. Such findings may even turn out to have useful applications in a transformed society, supposing that such a society will leave room for contested elections and party competition.

If it will not, many political scientists would argue that the project of emancipation will lead to less freedom rather than more, and less democracy. They would not be alone. Postmodernist philosophers, reflecting on how the Marxist project of emancipation miscarried in Bolshevik hands to produce a totalitarian regime, would decry any tendency to eliminate dissent in the name of the project, or reduce the variety of inquiries, whether the elimination is to occur after the project is carried to an end or beforehand. Critical social theorists could agree. They did not contemplate repressing other sorts of inquiry. They carried on a variety of inquiries themselves. Habermas, their chief heir, has made an explicit endeavour to find a place for all the sorts of inquiry sponsored by the three schools.

5 The impact of postmodernism

Disillusion with the project of emancipation surfaced in critical social theory itself as an aspect of disillusion with the Enlightenment. The Enlightenment fostered expectations of progress in many dimensions - not just in emancipation, but also in science, in technology, in material comforts, in rational and efficient social arrangements. It thus sponsored a number of what the postmodernist philosopher Jean-Francois Lyotard (§2) calls ‘grand narratives’, all of which postmodernists categorically repudiate. Michel Foucault did the same. Without ranking himself among postmodernists, Foucault was nevertheless a major source of ideas for them and an ally. Together he and Lyotard do as much as anyone to bring postmodernist ideas to bear upon the philosophy of social science.

Foucault and Lyotard draw points from the philosophy of language and the theory of knowledge to attack, along with grand narratives, ‘globalizing’ discourses of all kinds, and with them any claim to speak for, or even to aim at, a unified and comprehensive scientific view of the world. The most that can be hoped for, they say, are limited narratives and local bodies of knowledge, confined to transient social practices. Foucault has made ambitious and arresting studies of some of these, like psychiatry, clinical medicine, and penology. To combine his terminology with Lyotard’s, such practices are so many language games in which genres of discourse figure, perhaps more than one in a given instance, and employ locutions drawn from various ‘regimes’ of locutionary acts (phrases). Thus

clinical medicine employs declaratives (from one regime), interrogatives (from another), and imperatives (from a third) in discourse that is in genre both cognitive and therapeutic. The rules from the different regimes apply, and so do the rules distinctive of the different genres. In addition, the practice itself brings in rules, for example, a rule requiring that doctors make their diagnoses public before pathologists report on dissections in the same cases.

The knowledge gained within such a practice cannot be generalized. It would be out of place in another practice; and the findings of different practices cannot as they stand be accommodated at more general levels of knowledge. Foucault, for a time at least, went along with Nietzsche in treating every claim to knowledge as a demand for power. Disputes in social science, like disputes about knowledge in other connections, become conflicts of power, or of 'wills to truth'. Lyotard comes back repeatedly to disputes about knowledge turning upon issues (*différends*) that cannot be settled without (he holds) short-changing the ideas on one side or another. Researchers from one practice confront researchers from another; no general discourse is automatically available to mediate between them.

Some postmodernists might be content with taking guerrilla action against received views, darting out to attack generalizing pretensions whenever they parade by. Given the incessant tendency for styles of inquiry to congeal into rule-bound orthodoxy, disrupting them in this way can be useful and important. It does something to restore the nonchalance about rules and creative playfulness that in the young can be mistaken for mere fecklessness.

The guerrilla role would not suit Foucault, since at stake in his theory of knowledge are his own notable contributions to the histories of practices. Let us distinguish (1) what he does in these accounts; (2) what he describes himself as doing; (3) what he has to say in general about the character of knowledge and possibilities in the social sciences. Some of what he says in (2) may be at odds with (1); some of what he says in (3) may be at odds with (1) and (2) as well, at least in part. Yet the accounts brought forward under (1) come with claims of truth, or at least some approximation of truth. It is, for example, set forth as a truth that punishment as a practice of awe-inspiring spectacles gave way late in the eighteenth century to the practice of systematic imprisonment and surveillance. Moreover, an abundance of passages falling under (2) support saying that he describes himself as aiming to discover truths (in some sense opposed to overall scepticism) in his researches into practices.

Suppose that different views do mask the wills to truth and power of different persons and groups. Suppose, as Foucault maintains repeatedly, the views of the powerful prevail and other views are subjugated, though now and then there is a change in who holds power or a change in the assortment of views. A range of situations answers to this description, from totalitarian domination at one pole to an equal-power situation at the other. Could a general consensus about truth be brought about in an equal-power situation, unlikely though this might be?

It accords with the weight of what Foucault says in (3) that there could be a local and temporary resolution of the conflict. It might take the form of mutual acknowledgements among the contenders of there being 'some truth' in what other groups hold, and a joint statement listing those partial truths. In the intermediate situations, which are much more likely, local and temporary resolutions in the form of mutual acknowledgements could occur, though they would wring only limited concessions from the views of the powerful.

This not only accords with what Foucault says; it is essential to making sense of his campaign on behalf of 'subjugated knowledges'. Some headway - no doubt short of carrying all the way to the acknowledgements of an equal-power situation - can be made in redressing received patterns of domination in favour of giving at least some attention to the subjugated views. The defects of prevailing views will in consequence abate. If the prevailing view is that solitary confinement induces penitence in prisoners, the subjugated knowledge of the prisoners that solitary confinement enrages and embitters them could be invoked to modify the prevailing view.

Lyotard goes further in making room for advances in knowledge. He may exaggerate the frequency of *différends*. He does not consider at any length how different practices may intersect, as it seems they must do for there to be an issue between them; or how different practices may get along comfortably enough even when inconsistent. Consider astronomers in everyday life speaking of sunrise and sunset, and in poetical moments entertaining the idea of an animate moon ('queen and huntress, chaste and fair'). Yet Lyotard argues that *différends* can be surmounted by conceptual-linguistic innovation that is fair to each of them. Such innovation may have been required to straighten out the foundations of the calculus; and to reconcile quantum physics with logic and the principle of contradiction. One may doubt whether it is required to reconcile naturalistic social science with

interpretive, though the spectacle of Weber and Durkheim struggling for a view of social science integrating both might give pause on this point. In any case, Lyotard's idea that even *différends* can be surmounted with conceptual innovation amplifies the conception of local resolutions between conflicting truths in the form of mutual acknowledgements; and makes the conception more credible, wherever it is to be applied.

6 The relations between the schools re-examined

It is not just the furore created by postmodernism that threatens to unsettle the tidy picture of social science given by the three schools framework. A more explicit allowance for the hermeneutical concern with texts and for even more familiar subjective forms of experience has made it harder to see how interpretive studies bear affinities with naturalistic ones. It has made it even harder to see how naturalistic studies are an indispensable supplement. Yet anything lost in this regard can easily be made up.

Postmodernists like Foucault and Lyotard bring back the study of rules, in Foucault's case, with an emphasis more thorough-going than any other philosopher who has touched on the philosophy of social science. But if there can be models of systems of rules just as there can be models of regularities, then how far a model fits a real system, in regard to any universally quantified statement that figures in the model, is a matter for quantitative - statistical - study just as much with rules as with regularities.

With these considerations, the affinity of naturalism with interpretation returns. Not only does the affinity return; it returns in a form that is ready to receive the insistence of postmodern writers on truth being local, a matter of limited context that is always subject to supersession. For a model, if it has any success at all in matching a range of phenomena, may match only the phenomena of one society or one of its subgroups; and its success, moreover, is likely to be temporary. Not only will phenomena change, but what social scientists are looking for as important points of resemblance will change, too.

To which of the three schools should postmodernists be assigned? The rules that Foucault and Lyotard would have studied are rules of discourse, passing into rules of the practices in which the genres of discourse are embodied. Studying them would embrace the study of texts, in both literal and extended senses of the notion of text. Thus Foucault and Lyotard hook up with the interest in texts of the interpretive school and its hermeneutical component. Both Foucault and Lyotard, furthermore, are specially concerned with narratives, and narratives are a species of texts much attended to in the interpretive school.

On the other hand, neither Foucault nor Lyotard has much use for the forms of subjective experience more basic than narratives. Their animus against 'subjects' is directed in some passages against 'transcendental subjects' - ideal observers or agents who Foucault and Lyotard think are implicitly postulated in references to comprehensive knowledge. (Some readers would charge them with acting as transcendental subjects themselves when they make sweeping pronouncements.) In other passages, however, the animus seems to tell against having subjects at all: it is not persons who know or act or contend with one another, but discourses and their ingredients. The interpretive school cannot easily digest this point.

A more congenial home for it can be found in the critical school. The critical school has been all along inclined (though doing so belies some of its own work) to repudiate naturalistic inquiries. What needs to be raised to the critical level in its view has been interpretive social science. Foucault and Lyotard are interpretive enough to qualify; and their campaigns against orthodox views and grand narratives have precedents in the campaigns of the critical school itself against the Enlightenment and against ideology. Foucault and Lyotard generalize the critique: it is not just power reflected in the ideology of the ruling social class that dominates uncritical thinking; it is power everywhere, exerted by various groups and various practices contending with each other, that manifests itself in claims to truth. We can, so far as we can make sense of the idea, think of subjects, both transcendental and personal, as dropping out in the course of generalizing the critique.

Another way of generalizing the critique, which again would leave the three schools standing, along with the variations in them of styles of inquiry, would be simply to demand that every inquiry in social science choose questions that are more useful rather than less so. The standard of usefulness might refer to the urgency of current social problems. On a less intensely moralizing approach, running less danger of reducing the variety of inquiries, the standard might refer also to anomalies or gaps in current theories, or even to unsatisfied curiosity. Broad or narrow, the standard would do more to discriminate between inquiries than postmodernism is able to do given a

commitment to variety hard for it to modify. Inquiries that would make only a trivial difference to existing knowledge would fail the test of curiosity.

Some things that Foucault and Lyotard say, along with things voiced elsewhere on the postmodernist scene, are perhaps too devastatingly sceptical in intention or implication to be reconciled with the pursuit of social science in any sense. We may thus have to allow in the philosophy of social science for a school that (unlike any of the three schools in the framework) holds that social science is not possible. We do not have to join it.

Social science, history of philosophy of

The history of social science can conveniently be divided into four uneven periods, starting with the beginnings of both western science and philosophy in the ancient Greek polis *(city or state). It is fair to say, with qualifications, that the debate generated by the so-called Sophists, professional teachers of rhetoric in fifth-century Athens, established what would become the central questions for the future. The fundamental issue could be put thus: is society 'natural' or is it 'conventional', a historical product of human activities which vary across time and space? The Sophists, often abused in our standard histories, supported the conventional view. They held that even if it was anthropologically necessary that* Homo sapiens *live in societies, nature was silent about the character and ends of society. They thus defended what might be called 'cultural relativism'. By contrast Aristotle argued that some men were 'naturally' slaves and that all women were 'naturally' inferior; therefore slavery and patriarchy were dictated by nature, a view that prevailed well into the early modern period.*

Beginning in the sixteenth century we find a host of thinkers who reconceived the problem first raised by the Sophists. Many of them, for example, Hobbes, Rousseau and Adam Smith, held that 'by nature' humans had similar capacities and powers. Inequalities of power were 'artificial', wholly the result of historically established conventions. These writers also rejected the idea that society was a kind of natural community. For many of them, society existed by consent, the result of a contract.

The rejection of Aristotelianism was inspired by the Copernican revolution and the new physics of Galileo and Newton. This produced a self-conscious effort by early modern writers to articulate the idea of human science, modelled on the new physics. This critical idea was well put by the physiocrat Francois Quesnay: 'All social facts are linked together in the bond of eternal, immutable, ineluctable, inevitable laws, which individuals and government would obey if they were once known to them' (Randall 1940: 323).

The third period, roughly the nineteenth century, is then a battleground over both the idea of science and the idea of a human science. The paradigm provided by celestial mechanics was nearly overwhelming; even so, there was disagreement as regards its character, especially as regards the question of causality and explanation. Until very recently, 'positivists' have tended to prevail. That is, writers have followed Auguste Comte, who gave us the terms 'positivism' and 'sociology', and who held there were social laws which were to be analysed as 'relations of invariable succession': whenever this, then that.

As regards the possibility of a human science, consciousness and the problem of a free will raised the biggest questions. Materialists found nothing special about either; idealists did. Indeed a surprising amount of the most recent debates in the philosophy of the social sciences have their roots in these issues. If, as positivists insist, activity is governed by law, then what of human freedom? On the other hand, if humans have collectively made society and thus can remake it, then what is the nature of a human science?

1 Pre-modern philosophy of the human sciences

If we are to offer a history of the philosophy of the social sciences which begins prior to the twentieth century, we must admit some anachronism. Prior to this time, perhaps the only term in such a title with its present meaning is 'history'. Only in the nineteenth century was philosophy separated from 'science', and only in the early years of the twentieth century did 'social science' emerge as a set of disciplinary practices which could become the object of 'philosophy'. This is more than a quibble over terms, since issues regarding the nature and methods of acquiring knowledge of the human condition have again and again been contested.

In what follows, we admit the anachronism and sketch what earlier writers said about such inquiry. Moreover, since the lines between a philosophy of social science, a social philosophy, and a social science are also blurred, we consider these matters rather broadly. Until lines were drawn, there were no boundaries - and even today the boundaries are fuzzy.

It is well known that both western science and philosophy began in the West in ancient Greece. The so-called 'nature philosophers', Thales to Democritus, had included in their inquiry concerns about humankind and 'society'. But this was the special concern of the Sophists, who emerged in fifth-century democratic Athens as teachers who prepared men for political careers with instruction not only in rhetoric but also in 'wisdom' (*sophia*)

and in ‘virtue’ (*aretē*). It was in this context that the *physis*/*nomos* debate arose.

Nomoi (norms, laws, customs or conventions) establish what behaviour is to be sanctioned by the community. *Physis* (nature) was the object of inquiry of the Ionian ‘scientists’ but it also referred to the particular characteristics of things, for example, the nature or ‘essence’ of man. Aristotle summarized the debate: ‘Some people [for example, the Sophists] think that all rules of justice are merely conventional, because whereas a law of nature is immutable and has the same validity everywhere, as fire burns both here and in Persia, rules of justice are seen to vary’ (1968: 295). The implications are many: If humans are alike ‘by nature’, then why do *nomoi* treat them differently? Do *nomoi* originate from ‘agreements’, from the acts of legislators, or from gods? What is the *physis* of man? Is understanding *physis* sufficient for human society, or should we follow the sophist Protagoras, who argued that since *physis* could offer no clear prescriptions, human societies require humanly constructed *nomoi*? And if, as he also argued, all men are capable of sharing in the political (social) virtues, then perhaps the Athenians were right to allow every man to offer his advice regarding the *nomoi* of the city? (See Protagoras.)

For complicated historical reasons, the Sophists acquired a very bad name. Against them, Plato insisted that experience could not sustain an understanding of human society, still less an objective set of norms for the good human life. Plato did indeed raise some challenging problems for an empirical philosophy of humankind and elements of what we call ‘platonism’ still reverberate in discussions on the human sciences. Against the Sophists, Aristotle sought to found the human sciences in nature. He insisted that ‘the *polis* exists by nature’ and ‘a man that is by nature… cityless is either low in the scale of humanity or above it’ (1977: 9).

Although Aristotle offers immense insight relevant to the idea of a human science, particularly his overall ‘naturalistic’ approach to inquiry, his most striking and probably most influential appeals to nature were, perhaps, those that reinforced the prejudices of his time. For example, ‘to rule or to be ruled (*archai kai archesthai*) are conditions not only inevitable but also expedient; in some cases things are marked out from the moment of birth to rule or to be ruled’ (1977: 19). Those to be ruled were ‘barbarians’ and all women.

Most of the current vocabulary of the social sciences comes from Greek and Latin, however we must be careful about changing meanings. For example, ‘democracy’ and ‘economics’ share but faint resemblences to their original senses. Many other critical terms derive from Latin appropriations of Greek terms, for example, republic (*res publica*, *politeia*) and citizen (*civitas*, *politeian*). By the time of Polybius’ *Histories* (*c*.150BC), the Roman republic was huge by Greek standards. Similarly, Roman citizens bore little resemblance to the Greek original. Roman citizens had what we would call ‘civil rights’, but lacked utterly what defined a citizen for a Greek: as Aristotle had put it, a right ‘to participate in ruling and judging’.

We must forego examination of both Roman and medieval discussions of matters relevant here, except to notice that because in the Augustinian eschatology, redemption depended on grace rather than knowledge, historical modes of explanation were rejected. The Arabic reintroduction of Aristotle found expression, especially in the writings of St Thomas Aquinas and Marsiglio of Padua. With Aquinas, it was impossible ‘for the truth of faith to be contrary to principles known by natural reason’. Aquinas and Marsiglio shared with Aristotle the idea that existing things are arranged in natural hierarchies, including therefore humans and their communities. All had ‘natures’ which seek their *telos* or end. Finally, Renaissance humanism sought to recover, in Christian terms, the Roman concept of *virtus*, total human excellence. For early modern thinkers, Rome became an important case study.

2 The late Renaissance and early modern period

A great structural change had begun sometime in the late medieval period. It would ultimately produce modernity: the modern state and a capitalist social order. This would be the condition and problem for all subsequent social thinkers. These remarkable changes forced reconsideration of the problems of the human condition and especially, reconsideration of what are the prime philosophical questions of relevance here: what is the object of inquiry in the human sciences and how do we study it?

We identify two major shifts, which both represent efforts to break with the past. First, there was a rejection of the set of ideas which presumed that human associations were ‘natural communities’ which existed for the sake of realizing human virtues, secular or saintly. The introduction of the terms ‘society’ and ‘state’ suggest this. Several points of difference between the new states and older organizations can be noted. These new states had

‘governments’, itself a new term, which became increasingly concerned to maintain their autonomy not only versus other organizations of similar types, but also as regards organizations within their territories. With the development of the idea of government, the problem of legitimation arose in new forms. Similarly, *societas* acquired a new sense. Originally, a voluntary coming together for some purpose, ‘civil society’ could be used instead of ‘community’, or ‘republic’ which carried ancient connotations.

The second huge shift regarded the aims of ‘science’ (knowledge) and a new concern with method. The modern writers sought ‘inductively grounded’ practical knowledge. God was still maker of the universe, but he was to be known through his works, not through contemplation and faith. Similarly, if everything was ‘governed’ by law, ‘prevision’ and thus control was possible. Method-conscious Descartes well expressed the Faustian aspect of the new learning:

> it is possible to attain knowledge which is useful in life, and that, instead of that speculative philosophy which is taught in the Schools, we may find a practical philosophy by means of which, knowing the force and the action of fire, water, air, the stars, heavens and all other bodies that environ us, we can in the same way employ them in all those uses to which they are adapted, and thus render ourselves the masters and possessors of nature.
>
> ([1637] 1931: 119)

3 Machiavelli and Bodin: redefining the polity

Exemplifying these changes, Machiavelli was perhaps the first modern ‘social scientist’. Proceeding ‘inductively’ and convinced that men of virtue could tame *fortuna*, he began his *Discourses* with the complaint that for all their admiration of the ancient writers, his generation had failed to appreciate the examples provided by antiquity. But he departed sharply from ancient writers as regards the aims of political organization. It was, he insisted, securing the ‘liberty’ (independence) and ‘security’ of the body politic. Today an uncritical given, he seems to be the first to hold that this was the defining condition of associated life.

Machiavelli suggested a choice between two sorts of republics, one that ‘desires to extend its empire, as Rome’, the other, as Sparta or Venice, that ‘confines itself merely to its own preservation’. But in the new environment, the only real choice was Rome.

It is in this context, as well, that his more famous *Prince* should be understood. As Machiavelli had said in his *Discourses*: ‘A wise mind will never censure any one for having employed extraordinary means for the purpose of establishing a kingdom or constituting a republic’ (1950: 138-9). The message of the *Prince* is technical, not moral. For the Greek, the citizen was the government, for citizens ruled. But Machiavelli assumed that the state (government) and ‘the people’ are distinct. Public persons constitute a government which exists to serve the governed persons in their private lives. Government may do this well or badly, but it cannot do it well if decisions are persistently opposed, and if it cannot act for the body as a whole. As he put the matter: government is the management of citizens so that ‘they are neither able nor disposed to oppose you’ (1950: 358). Accordingly, the governors of any well-ordered state will and should quite normally employ measures which, from the standpoint of common morality, are immoral.

What, however, was the character of this new kind of entity? Writing in 1576, Bodin answered:

> Ancient writers have called Common weals, Societies of men assembled to live well and happily together. Which as it may serve for a description of a Citie, so can it not stand for a true definition of a Commonweale.
>
> ([1576] 1962: 3)

It was not necessary that members of a commonwealth live ‘happily’ or even that they be well governed. Moreover, as individuals pursue many ends, so do commonwealths. The proper definition of a commonwealth required only that members be ‘governed by a puissant sovereign of one or many rulers; albeit that they differ in lawes, language, customes, religions, and diversity of nations’ ([1576] 1962: 49). Missing entirely is the idea that a polity is a natural community, a ‘family’ with common ends.

4 Two views of society: Hobbes, Locke and Adam Smith; Rousseau and Vico

The *nomos/physis* debate anticipated what we can now clearly identify as the two fundamentally different and still competing metatheoretical assumptions regarding human associations, one ‘holistic’, the other ‘individualist’. The former idea will not lose its persuasiveness, recurring in variant forms in Vico, Rousseau, Herder, Hegel’s variant descendants, and Durkheim. The newer conception, associated with liberal or ‘utilitarian’ social theory is presupposed by Hobbes, Locke, Adam Smith, Bentham, Mill, Herbert Spencer, Pareto and, in its modern recent variations, rational choice theory (including here modern microeconomics). The choice between the two entails a host of other important differences.

The idea that society is but an aggregation of individuals united by agreements to accept the authority of certain conditions for acting is brilliantly developed by Thomas Hobbes, who also broke decisively with the past in postulating both a universal human nature and the idea that ‘by nature’ humans differ little in terms of their powers and abilities. Postulating endless desire, individuals everywhere and everywhen ‘seek power after power’. Accordingly, the ‘natural condition of mankind’ is a condition of war. But if individuals alienate their ‘right to all things’ to a sovereign power, peace can be secured. Since this is the ‘rational’ thing for mutually self-interested individuals to do, civil society is ‘explained’ and sovereign power is justified as the cement of society. Hobbes was, accordingly, the first ‘law and order’ theorist.

Hobbes, Locke and Rousseau are thought of as ‘contract’ theorists, but the differences are critical. Perhaps Locke’s greatest achievement, usually not acknowledged, was his ‘explanation’ of private property, which, it seems, is the only one available that is also a serious defence (see Locke, J. §10). Locke believed that God had ‘given the earth to Mankind in common’, but he rejected Hobbes’ idea that the right to property was merely conventional. If our bodies and, thus, our labour was ours, what we ‘mix our labour’ with is ours. Although this is a highly problematic idea, neither Proudhon, who believed that property was theft, nor Marx would have cause to disagree. The problem comes when the two moral conditions imposed on the free appropriation from nature are put into question. We should not waste, nor can we appropriate when such appropriation puts others at a disadvantage. Locke argued that money was introduced by our consent. This allowed unlimited appropriation. What is produced in excess of need can be sold to those who are unable to appropriate freely from nature. Since it is their right to sell their labour power to landowners, no one, presumably, is put at any disadvantage. Class inequality, accordingly, was an unintended consequence of the voluntary introduction and use of money. And all this prior to the ‘consent’ which constituted civil society.

Rousseau’s views stand in marked contrast. He shared with Vico the view that one could not ‘explain’ society in terms of the ‘contract’ and he further suggested that the psychological qualities attributed to mankind by Hobbes and the liberals who followed him were social constructions (see Rousseau, J.-J.). In his *Discourse on the Origins of Inequality* (1755), Rousseau bitterly criticized his predecessors on just these grounds. For him, ‘society’ emerged ‘naturally’, the result of the development of language. The true founder of civil society, he ironically wrote, was the person who having staked out an area of land, declared, ‘This is mine’ and found people ‘simple enough’ to believe him. Rousseau seems to have been the first to argue that human history is largely the product of unintended consequences, and he is one of the very few who insisted that the changes were not progressive. For him, humans had unwittingly forged chains which imprisoned them. This was largely the result of the interdependence which genuine humanness had brought. The solution was the social contract. Since sovereignty was for him inalienable, and governments had only executive power, Rousseau, a radical democrat, insisted that unless people take collective control of the conditions of their lives, tyranny is quite inevitable (see Contractarianism §6).

We can here compare Vico’s *The New Science* (1725). For Vico, culture and its artefacts are all creations of human consciousness. He thus insisted, anticipating Dilthey, that humans can understand themselves and all that they have created. Like Rousseau, but no democrat, Vico rejected ‘contract’ theory as incapable of explaining society. He argued that history, which was cyclical, set different problems for different ages (see Vico, G.). Marx was impressed by Vico’s view that an ‘inductive’ historical ‘science’ could emancipate people by emancipating them from superstition and by displaying their true nature.

Adam Smith’s rational individualism puts him in direct opposition to Vico and Rousseau (see Smith, A.). If for Hobbes statutory law turns the violent competition of ‘the natural condition’ into peace, and if for Rousseau, the division of labour is the fundamental cause of human self-alienation, for Smith, by means of ‘the invisible hand’,

the division of labour gives ‘self-love’ distinctly beneficial unintended consequences. Indeed, Smith made the effort to explain the division of labour with one universal psychological principle: the ‘propensity to truck, barter and exchange’. By this time, Smith could take private property for granted, along with the idea, still uncritically assumed, of the market.

If Smith was the founder of political economy, it is also important to notice that he did not conceive of its domain narrowly. When *The Wealth of Nations* was published in 1776, ‘political economy’ referred to ‘the art or practical science of managing the resources of nations’. This is why some 60 per cent of *The Wealth of Nations* is historical and sociological, and why from the point of view of modern economic thinking this portion is utterly irrelevant.

John Stuart Mill’s 1829 essay, ‘On the definition of political economy; and the method of investigation proper to it’ (1844) settled several of the then unsettled questions. Thereafter, political economy would be thought of as an abstract, ahistorical science which treats the ‘laws’ that regulate the production, accumulation and distribution of commodities (see Economics, philosophy of).

5 Progress and positivism: Comte and Herder

Auguste Comte was an heir to the French Enlightenment, but between Turgot and Montesquieu and Comte’s *Cours de Philosophie Positiv* (*The Positive Philosophy of Auguste Comte* [1830-42]) came the French Revolution and the rumblings of anarchism and communism. Not only was the thought of Rousseau and Montesquieu rendered irrelevant, but the events raised the question of whether there could be both order and progress. Comte said yes - if politicians would accept the truths of science, understood by him in distinctly positivist terms (see Comte, A.).

Comte held that there are three fundamental ‘epochs of the mind of the race’, three stages: the theological or fictitious, the metaphysical or abstract, and the scientific or positive. The theological mind ‘supposes all phenomena to be produced by the immediate action of supernatural beings’. The metaphysical mind ‘supposes, instead of supernatural beings, abstract forces… inherent in all things, and capable of producing all phenomena’. The positivist mind, by contrast, has not only ‘given over the vain search for Absolute notions, the origin and destination of the universe’, but also ‘the causes of phenomena’. Instead, it ‘applies itself to the study of their laws - that is, their invariable relations of succession and resemblance’ (Comte [1830-42] 1875: I, 2).

There is here a clear contrast between a positivist sense of law and causality and a distinctly realist conception - causes as productive powers. A realist conception, ‘metaphysical’ for the positivist, is common to ordinary thinking, and shorn of what are, today, unwelcome teleological commitments, it has been given increasing attention since the 1970s. According to positivists, we do not observe productive powers ‘inherent in things’. Following Hume, we ‘observe’ relations of succession: if this, then that. A realist and teleological view was argued by Aristotle and in the tradition which followed him. It is beautifully illustrated, with many of its problems, in the writings of Johann Herder, one of those who articulated a philosophy of human science which fell by the wayside.

Influenced by Rousseau and Montesquieu, Herder expressed a desire to be ‘the Newton of history’. He begins with the realist idea that ‘whenever we observe a power (*Kraft*) in operation, it is inherent in some organ and in harmony with it’. But ‘power as such is not open to investigation, at least not by our senses. It exists for these by its manifestations… ’. This is then applied: ‘The human essence - *Humanität* - is not ready made, yet is potentially realizable’ ([1794-91] 1969: 266). As with individuals, linguistically interacting people - *Völker* - have environments, ‘climates’, with which they epigenetically transact. Moreover, ‘whatever the climatic influence, every human being, every animal, every plant has a climate of its own; for each absorbs and adapts to external influences in its own organic manner’ (Barnard 1965: 120). A multiplicity of equally valuable *Völk*, each in transaction with its ‘climate’, has created a human world, many concrete realizations of our shared *Humanität*. Indeed, there are no races since ‘complexions run into each other… *in toto* they are, in the final analysis, but different shades of the same great picture which extends though all ages and all parts of the earth’ (Herder [1794-1] 1969: 284). Herder’s vision was anarchist and cosmopolitan, not statist and chauvinist: each *Völk* has its own ‘spirit’, its own ‘genius’. Herder emphatically rejected Eurocentric notions of progress, which for him were but ‘figments’, constructed from ‘embroidered or invented facts’.

Herder lost, Comte’s Eurocentrism and positivist conception of a human science carried the day. Comte articulated what are, appropriately, the defining ideas of positivism: not only should we reject the search for causes as

productive powers, but also, 'what is now understood when we speak of an explanation of facts is simply the establishment of a connection between single phenomena and some general facts… ' (Comte 1875: I, 2) - what is now called 'the covering law model of scientific explanation'.

But not all of Comte's views carried the day. Since humans are essentially social, there is no science between physiology and sociology. Second, not only is society not 'decomposible into individuals' but 'there can be no scientific study of society, either in its conditions or its movements, if it is separated into portions, and its divisions are studied apart' (Lenzer 1975: 228). Comte would not have approved of the present disciplinary division of the human sciences, nor its characteristic 'methodological individualism' (see Positivism in the social sciences §1).

6 Mill's *Logic*

This is not true of J.S. Mill, who was writing his *System of Logic* (1843) when he read Comte. While he accepted the inevitability of progress, he was dissatisfied with Comte's law of progress. If it was a law, then, it had to be 'invariant' and therefore there had to be as Comte had said, 'a necessarily invariable development of all humanity'. Mill could not see how this was possible.

Mill distinguished 'laws of nature' from 'empirical laws'. With Comte, Mill would leave to the metaphysicians any talk about 'the ultimate mode of production of phenomena, and of every other question regarding the nature of "Things in themselves"' ([1843] 1930, III, ch. V). But if 'empirical laws' are 'uniformities which observation and experience has shown to exist', what makes them different from laws? Mill distinguishes 'ultimate' from 'derivative laws'. Derivative laws are the result of 'a collocation of causes'. Derivative laws are 'resolved' into ultimate laws and are, by subsumption, explained by them. The law of inertia is 'ultimate', an unexplained explainer. Kepler's laws are derivative.

This may not do, especially if the covering law model of explanation is rejected. One might ask, for example, whether there are any empirical uniformities which are not the product of a collocation of causes? And, if so, perhaps the problem resides in the analysis of causality?

Mill affirmed that there were 'laws of society', but they 'can be nothing but the laws of the actions and passions of human beings' ([1843] 1930, VI, ch. VII). In addition, then, to the universal 'laws of the mind', there were 'derivative laws', the object of 'ethology', Mill's science of character. History, then, can only be explained as 'collocations of causes', a point made by Weber who with greater consistency also emphatically rejected the covering law model of explanation.

7 Karl Marx: one human science?

Although every author discussed in this entry has been variously interpreted, the situation is especially difficult as regards Marx's philosophy of the human sciences (see Marx, K.). Not only were many of his important texts unknown until this century, but different interpretations give rise to different Marxist politics. Two widely diverging interpretations are first, the conventional understanding, shared by the mainstream on both sides of the historic confrontation between capitalism and Marxian socialism, and the second which became prominent in the 1970s.

On the 'orthodox' view, Marxism is a positivism and a materialism. As a positivism, it has a deterministic theory of history in which societies must pass through stages. As a materialism, it holds that 'the economic structure of society [is] the real foundation on which arises the legal and political superstructure and to which corresponds definite forms of social consciousness'. A 'dialectic' then explains change. Thus, 'at a certain stage of development, the material productive forces of society come into contact with existing relations of production…. From forms of development of the productive forces these relations turn into fetters. Then begins an era of social revolution' ([1859] 1904:12). As in Comte, agency drops out.

On the alternative interpretation, Hegel is taken far more seriously, but on this reading, Marx rejects the idealism/materialism problematic, offering instead a naturalism that acknowledged the active constitutive side of idealist epistemology while holding to the causal demands of the independently existing 'material' reality. On this view, Marx rejected the reified abstractions of idealism. Thus, superstructural properties, for example, law and ideology, have no independent existence and, versus the 'ideologists', there can be no independent histories of law

and ideas. There are only 'real individuals, their activity and the material conditions under which they live, both those which they find already existing and those produced by their activity' (1947: 7). This text, from *The German Ideology*, published only in 1883, along with the much later published *Paris Manuscripts* and *Grundrisse* offer the best textual support for this strongly agency-centred reading of Marx's philosophy of social science. It is summarized in the oft-quoted text from Marx's *Eighteenth Brumaire*: 'Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances directly encountered, given and transmitted from the past' ([1852] 1963: 15). Similarly, 'stage theory' is rejected: As Marx wrote in response to a reviewer of *Capital*: 'my critic… feels that he absolutely must metamorphose my historical sketch of the genesis of capitalism in Western Europe into an historico-philosophical theory of the general path every people is fated to tread, whatever the historical circumstances in which it finds itself… But I beg his pardon' ([1877] 1942: 354).

Following on this interpretation is a strongly realist reading of *Capital*. Volume 1 provides an abstract model of capitalist reproduction, shorn of all the particularities and contingencies which shape concrete capitalist societies. For example, it is a system-law that by virtue of the structural relations which define capitalism, there will be a tendency for the falling rate of profit. But this tendency may not be actualized, just as the inertial tendency of a planet to move rectilinearly is not realized. There are other causes at work in the world: For example, capitalists, struggling to reduce costs (and thus reducing the rate of exploitation) will move capital where labour is cheaper.

Finally, since conscious beings make history, it becomes critical to consider how their understanding enters into social reproduction/transformation. In all societies, production is social and people are more or less interdependent. But the form which products take when production is organized for generalized exchange is the commodity. Under this condition, however, 'the relations connecting the labour of one individual with that of the rest appear, not as direct social relations between persons at work, but as what they really are, material relations between persons and social relations between things' ([1867] 1970: I, 1). Such 'fetishism' is essential to capitalist reproduction, and on this reading, its analysis is continuous with his earlier analysis of 'alienation'.

8 Dilthey and historicism

Marx and Engels asserted that 'we know only one science, the science of history'. But as 'naturalists', this did not require a fundamentally different epistemology. The writings of Wilhelm Dilthey are in the background of most subsequent 'anti-naturalisms' in the philosophy of the social sciences.

For him, the natural sciences had emancipated themselves from metaphysics - in positivist fashion. This would not do for *Geisteswissenschaften*, a term introduced into German as a translation of Mill's 'moral sciences'. In the *Geisteswissenschaften* we are not dealing with 'representations' of an unknowable external reality, but with the objects of consciousness themselves. As Iggers writes: 'Understanding [*Verstehen*] is possible… because life "objectivates" itself in such institutions as the family, civil society, state and law, art, religion and philosophy. As products of life and spirit, these institutions can be understood' (1983: 139).

This 'solution' to the problem of the foundations of knowledge in the human sciences is not without difficulties, which is acknowledged by Dilthey. Thus, 'this task led me to the most general problems; a seemingly insoluble contradiction arises if we pursue historical consciousness to its last consequences. The finitude of every historical phenomenon, whether it be a religion, an ideal, or a philosophic system, hence the relativity of every sort of human conception about the connectedness of things, is the last word of the historical world view' (Iggers 1983: 143-4).

For Hegel, 'spirit' was 'objective' and constituted a specific stage in historical development. This could overcome both subjectivism and relativism, but while Dilthey seems to have moved in this direction, it is doubtful that he finally did overcome the 'seemingly insoluble contradiction'.

9 Max Weber: human science as concrete

A consequence of the Cold War was the view that Marx and Weber polarize on the idealism/materialism dichotomy. There is good reason, however, to believe that Weber, influenced by Neo-Kantian philosophy also rejected this dichotomy. For him, *Verstehen* (understanding) was unproblematic, 'a transcendental assumption' of both everyday life and of any attempt to understand it. Like Marx, Weber rejected Hegelian versions of history in which concrete reality 'emanated' from abstract ideas which had independent existences. Finally, while Weber

rejected the reductionist monocausal understanding of history put forward by the Second International, one of the most important aims of the journal he edited was 'the advancement of the economic interpretation of history'.

Weber made a central distinction between two kinds of sciences: abstract or nomothetic and concrete or historical, a distinction which in variant forms begins with Otto Ranke and is found in Dilthey, Rickart, Menger, Simmel and Windelband, who gave us the pair, 'nomothetic/idiographic'.

For Weber, the two kinds of science satisfy different interests and require different methodologies, but crucially the distinction does divide the natural and human sciences. The purpose of 'nomological science' is 'generalized abstraction' and the elimination of 'purely contingent facts'. Its concepts are 'generic'. Thus, the laws of pure mechanics are true of everything; but such knowledge is none the less 'worth knowing'. The human sciences could be nomological, but assertions true of all societies would not be interesting. Indeed, 'the theses that the ideal of science is the reduction of empirical reality to "laws" is meaningless'. The concrete sciences have as their aim 'the descriptive reproduction of reality in its full actuality'. We want knowledge of things 'which we regard as essential because of their individual peculiarities' (Weber [1903-6] 1975: 57). In the human sciences, we need, not generic concepts, but ideal-type concepts, rich in intention and particular in extension. An ideal-type is 'like a utopia which has been arrived at by the analytical accentuation of certain elements of reality', including 'typical modes of action' (Weber[1904] 1949: 90). The construction of such concepts is the main task of sociology. Ideal-types solve the problem of causal explanation because they enable us 'to become aware of the characteristic meaning of single, concrete cultural elements together with their concrete causes and effects' (Weber [1904] 1949: 65). It follows also that explanation is not by subsumption under law.

10 Spencer and Engels: two monisms

While Darwin's *Origin of Species* (1859) surely established 'evolution' as a prominent way of thinking, Herbert Spencer was already insisting that evolution ensured that 'progress… is not an accident, but a necessity'. Spencer 'induced' one evolution 'going on everywhere after the same manner….There is a change from an incoherent homogeneity to a coherent heterogeneity, accompanying the dissipation of motion and the integration of matter' ([1862] 1976: 325). As regards society, this issued in an ever-perfecting functional harmony: 'As surely as the tree becomes bulky when it stands alone, and slender if one of a group… so surely must the human faculties be moulded into complete fitness for a social state… so surely must man become perfect' ([1850] 1897: 32).

Spencer's views could be classified as both positivist and monistic naturalist. They compare in this regard to those of his contemporary, Friedrich Engels. The 'old materialists' (Dühring, Büchner) could not explain novelty. This could be overcome with a 'dialectical' materialism: 'the science of the general laws of motion and development in nature, human society and thought' (Engels [1885] 1939: 155). These laws 'reduce' to three: 'the law of the transformation of quantify into quality, and vice versa; the law of the interpenetration of opposites; [and] the law of the negation of the negation' ([1927] 1940: 26). These are all in Hegel, but his 'mistake lies in the fact that these laws are foisted on nature and history and laws of thought, and not deduced [inferred] from them' ([1927] 1940: 26).

Engels, like Spencer, is aware that his super-generalizations are abstract and do not 'say anything concerning the particular processes of development' ([1885] 1939: 154), nor for the same reason, do they say anything about the particular mechanisms of these processes. But if so, then as with Spencer, the most obvious problem is their vacuousness.

11 Pareto and Durkheim: two positivisms

Gustav Schmoller lost the *Methodenstreit* (dispute of methods) to Karl Menger and the new neoclassical economists. As Schumpeter (1954) has argued, for all the technical innovations, marginalism did not represent a paradigm shift from earlier classical political economy. Three differences, all consequences of a more self-conscious positivism, can be noted. First, hints of realism as regards causality largely disappear. Second, as Pareto put the matter, 'establishing a theory is something like passing a curve through a number of fixed points' ([1906] 1971: 31); and third, 'normative propositions' must be sharply distinguished from 'existential propositions'.

Durkheim and Pareto both accepted positivist versions of law and theory. In consequence, both contributed to the

idea that quantitative social research was the main task of the social scientist. Both thought of a society as a system although they differed fundamentally on its character.

Pareto argued that ‘the form of society is determined by all the elements acting upon it, and it, in turn, reacts upon them’ ([1915-19] 1935: para. 2060). The economic system, the domain of ‘rational’ behaviour, is a subsystem of the social system, embedded in a natural environment. But features of this are accounted for indirectly, since their effects are felt on individuals, the units of the social system. Individuals are possessed of ‘sentiments’, Pareto’s term for the various manifestations of non-rational behaviour, so that action is a joint outcome of the ‘rational’ and ‘non-rational’. Generalizing general equilibrium theory, Pareto warmly endorsed the dream of positivist social science:

> In order thoroughly to grasp the form of society in its every detail it would be necessary to know what all the very numerous elements are, and then to know how they function - and that in quantitative terms… The number of equations would be equal to the number of unknowns and would determine them exhaustively.
>
> ([1915-19] 1935: para. 2062)

In contrast to Weber (and more recent complexity theory), the social system, like the system of planets, is a closed system. Accordingly, the ‘laws’ of society can be mathematical functions of variables. This vision, usually unspoken, still pervades inquiry in social science.

Émile Durkheim saw no usefulness in economics, nor for that matter in any of the ‘utilitarian’ sorts of theory which Hobbes had initiated. He agreed with Comte, also, that ‘since it does not call for one social form rather than another’, psychology cannot explain any of them ([1895] 1938: 108). Instead, there are irreducible ‘social facts’ - that is, ‘ways of acting or thinking with the peculiar characteristic of exercising a coercive influence on individual consciousness’ ([1895] 1938: liii). Social facts are ‘external’ and depend on the collective consciousness which has its own laws. This road, which connects also to Platonism, leads directly to twentieth-century structuralism.

Durkheim was a functionalist, but he was also a critic of the functionalism which he attributed to Comte and Spencer (see Functionalism in social science). Once having shown that some social form was ‘useful’ in so far as it satisfied some ‘need’, they were content. Missing was an account of ‘how it originates or why it was what it is’ ([1895] 1938: 90). Moreover, a social fact can exist without being useful at all. But Durkheim did not escape the progressivism of Comte and Spencer. Societies, like organisms, have a lawful ‘development’. ‘*Anomie*’ was ‘abnormal’, the product of the breakdown of religion and authority which had subordinated modern industry. Indeed, ‘what is needed if social order is to reign is that the mass of men be content with their lot… And for this, it is absolutely necessary that there be an authority whose superiority they acknowledge and which tells them what is right’ (1959: 200).

12 The twentieth century

Employing available intellectual materials and exploiting the new opportunities in the new institutions of higher education in the USA, Americans constructed the prevailing disciplinary division of the human sciences (Manicas 1987). By the early 1920s these were reconstituted on a manifestly positivist reading of ‘hard science’. This was then profoundly reinforced by ‘logical positivism’, imported from Vienna.

By the 1950s, the philosophical debate had polarized between positivists and a minority of anti-naturalists who rejected the idea of a human science, at least as understood by positivists (Natanson 1963). Thus Popper, Hempel, Brodbeck and others continued to defend the relevance of the covering law model for social science, even while it was being attacked by sympathetic critics. Except for marginalized Marxists and a few non-Marxist dissenters, for example C.W. Mills (1959), it was business as usual in the departments of the academy.

Kuhn (1967) devastated foundationist epistemology and generated a radical sociological challenge to it (Barnes 1982), but he did not raise questions about either causality or explanation. A third alternative, a non-positivist, realist understanding of science, did. Hinted at by Toulmin, Scriven, Sellers, Hanson and others, it was given perhaps its first clear expression by Harré (1970) and then by Bhaskar (1975). It was applied to social science by Harré and Secord (1973) and influenced by the fresh readings of Marx, by Keat and Urry (1975), Benton (1977), Bhaskar (1979) and Outhwaite (1983).

This enabled a reconsideration of the ancient ontological debate regarding the nature of society. It continued to be polarized across two dimensions, on the one hand between 'methodological individualists' standing in the tradition of Hobbes (Gellner 1956; Watkins 1957; Homans 1967) and functionalist 'holists', generally influenced by Durkheim (Mandelbaum 1955). On the other hand between 'subjectivist' approaches in, for example, Schütz (1966) and Garfinkel (1967) and variant 'objectivist' structural approaches which included the very different views of, for example, Lévi-Strauss (1962), Althusser (1965) and Alexander (1987).

The more or less explicitly realist efforts to reconcile these turned on re-examining the status of 'agents' as conscious beings engaged in practical activity, an extended gloss on Marx's remark that persons make history but not with materials of their choosing. On Bhaskar's 'transformational model of social action', social forms predate the actions of agents which reproduce and transform them. Giddens' 'structuration' view (1976; 1980), less explicitly realist, defines social structure in terms of the 'rules and resources' available to agents in acting. Social structure thus has but 'virtual existence'.

Some of the same polarities were confronted in re-examining the question of culture (Foucault 1969; Bourdieu and Passeron 1970; Williams 1977). Feminist voices (Harding and Hintikka 1983) were also increasingly important. In turn, 'cultural studies' was being influenced by developments in 'postmodern' theory, including here a 'decentring of the subject' and a strongly anti-naturalistic turn towards 'discourse' (Lacan 1977; Derrida 1970). As regards the philosophy of the social sciences, by the 1990s the hegemony of positivism could no longer be taken for granted.

Gellner, E. (1956) 'Holism Versus Individualism', repr. in *Readings in the Philosophy of the Social Sciences*, ed. M. Brodbeck, New York: Macmillan, 1968. (This volume well represents the hegemony of positivist philosophy of social science during this period.)
Giddens, A. (1976) *New Rules of Sociological Method*, London: Hutchinson.(In this rather brief book, Giddens discusses critically the main themes and some of the main figures of philosophy of social science: Schütz, Garfinkel, hermeneutics, Durkheim, Parsons and Marx and concludes with a criticism of positivism.)
Giddens, A. (1980) *The Constitution of Society*, Berkeley, CA: University of California Press.(Giddens' most thoroughgoing statement of his 'structuration' theory - his effort to resolve the continuing dichotomies of social theory. Important.)
Harding, S. and Hintikka, M. (eds) (1983) *Discovering Reality*, Boston, MA: Reidel.(One of the better collections of interventions in epistemology by feminists.)
Harré, R. (1970) *The Principles of Scientific Thinking*, Chicago, IL: University of Chicago Press.(Perhaps a 'Copernician revolution' in the philosophy of science; it provoked a range of new 'realist' thinking.)
Harré, R. and Secord, P. (1973) *The Explanation of Social Behavior*, Oxford: Blackwell.(The 'ethnogenic' approach of this book offered a clear alternative to most mainstream conceptualizations.)
Herder, J.G. (1794-91) *J.G. Herder on Social and Political Culture*, trans. ed., and with an intro. by F.M. Barnard, Cambridge: Cambridge University Press, 1969.(Very useful for the general student.)
Hobbes, T. (1651) *Leviathan*, New York: E.P. Dutton, 1950.(The source of much modern political theory.

Indispensable.)
Homans, G. (1967) *The Nature of Social Science*, New York: Harcourt Brace.(An important work by a recent 'behaviouralist' critic of 'holistic' (structuralist) views of sociology.)
Iggers, G.G. (1983) *The German Conception of History: the National Tradition of Historical Thought from Herder to the Present*, Middletown, CT: Wesleyan University Press.(An excellent overview of this critical history.)
Keat, R. and Urry, J. (1975) *Social Theory as Science*, London: Routledge & Kegan Paul.('Realist' theory.)
Kerferd, G.B. (1981) *The Sophistic Movement*, Cambridge: Cambridge University Press.(Gives a sympathetic account of the central issues discussed in §1, above.)
Kuhn, T. (1967) *The Structure of Scientific Revolution*, Chicago, IL: University of Chicago Press, enlarged edn, 1970.(A book which upset the long legacy of empiricist, positivist thinking about the nature of science, including social science. Essential reading.)
Lacan, J. (1977) *Ecrits, A Selection*, trans. J. Sheridan, New York: Norton, 1977.(A 'decentring of the subject' which draws on Freud's theory of the unconscious. Often cryptic.)
Lenzer, G. (ed.) (1975) *Auguste Comte and Positivism: The Essential Writings*, New York: Harper, 1975.(A very convenient student's edition. Judicious editing.)
Lévi-Strauss, C. (1962) *The Savage Mind*, Chicago, IL: University of Chicago Press, 1966.(A strongly 'structuralist' but anti-functionalist approach to social science.)
Locke, J. (1690) *Two Treatises of Civil Government*, with an intro. and *appartus criticus* by P. Laslett, 2nd edn, Cambridge: Cambridge University Press, 1967.(The foundation of modern constitutionalism and liberalism.)
Machiavelli, N. (1515, 1527) *The Prince and the Discourses*, New York: Modern Library, 1950.(*The Discourses* are less well known than *The Prince* since it was the latter which has shocked readers; but contrary to widespread opinion, for reasons set out in *The Discourses*, most leaders of modern states have learned from Machiavelli.)
Makkreel, R.F. (1975) *Dilthey: Philosopher of the Human Studies*, Princeton, NJ: Princeton University Press. (Perhaps the most important recent commentary on Dilthey.)
Mandelbaum, M. (1955) 'Societal Facts', *The British Journal of Sociology* 6 (4): 305-17.(A 'classic' defence of 'holism' against 'methodological individualism'.)
Mandelbaum, M. (1971) *Reason, Man and History*, Baltimore, MD: Johns Hopkins University Press.(Perhaps the best review of nineteenth-century writers relevant to the human sciences. Important and accessible.)
Manicas, P.T. (1987) *A History and Philosophy of the Social Sciences*, Oxford: Blackwell.(A fuller treatment of the history beginning with the eighteenth century.)
Marx, K. (1852) *The Eighteen Brumaire of Louis Bonaparte*, New York: International Publishers, 1963.(Probably the best concrete discussion of class and its role in social change in the corpus of Marx's volumious writings.)
Marx, K. (1859) *A Contribution to the Critique of Political Economy*, Chicago, IL: Charles H. Kerr, 1904.(The 'Preface' has been extremely influential in defining the character of Marx's 'historical materialism'.)
Marx, K. (1867) *Capital*, vol. 1, London: Lawrence & Wishart, 1970.(Certainly one of the most influential books of social science, very much incorporated into current theory - by Marxists and non-Marxists alike.)
Marx, K. and Engels, F. (1883) *The German Ideology*, New York: International Publishers, 1947.(For many interpretators, this is the most critical text in gaining an understanding of 'historical materialism'.)
Marx, K. and Engels, F. (1877) *Marx and Engels Selected Correspondence*, New York: International Publishers, 1942.(One of several collections.)
Mill, J.S. (1844) *Essays on Some Unsettled Questions of Political Economy*, 2nd edn, Clifton, NJ: Augustus Kelly, 1974.(Now little read, these lively essays show that Mill would not have approved of subsequent developments in the philosophy of 'economics'.)
Mill, J.S. (1843) *System of Logic*, 8th edn, London: Longman, 1930.(A monumental, influential and still useful effort to set out the 'logic' of the human sciences. Introduces his famous 'methods'.)
Mills, C.W. (1959) *The Sociological Imagination*, Harmondsworth: Penguin.(The title, now very much in the literature, is often hardly taken seriously; a hardnosed attack on 'abstracted empiricism' and 'grand theory', both still very much in evidence.)
Natanson, M. (ed.) (1963) *Philosophy of the Social Sciences*, New York: Random House.(The editor made his selections based on the assumption that there were two polar positions underlying the social sciences, an 'objective' versus a 'subjective' point of view. Contains most of the most important essays which define this debate. Very influential.)
Outhwaite, W. (1983) *New Philosophies of Science: Realism, Hermeneutics and Critical Theory*, New York: St Martins Press, 1987.(Parallels in some ways Benton 1977.)

Pareto, W. (1915-19) *Mind and Society*, New York: Harcourt, 1935.(This massive and often tedious work is now largely forgotten even while there is a considerable residue of its driving vision.)

Pareto, W. (1906) *Manual of Political Economy*, New York: Kelly, 1971.(A clear statement of Pareto's philosophy of social science.)

Passmore, J. (1957) *A Hundred Years of Philosophy*, Harmondsworth: Penguin, 1968. (Certainly the best account of the often ignored late nineteenth-century 'philosopher/physicists' whose views powerfully influenced the idea of science which was appropriated by the emerging modern social sciences. Passmore is a reliable expositor of all the figures he treats.)

Randall, J.H. (1940) *The Making of the Modern Mind*, Cambridge, MA: Riverside Press.(Randall gives a superb account of how thinking about society shifted from the medieval period to modernity. Very readable.)

Ross, D. (1991) *The Origins of American Social Science*, Cambridge: Cambridge University Press.(A detailed study of the critical period, 1870-1929, of the constitution of US disciplinary social science.)

Rousseau, J.-J. (1755) *The Social Contract and Discourses*, trans. G.P.H. Cole, New York: E.P. Dutton, 1950. (Rousseau's writings are essential, but are less often read in terms of philosophy of social science.)

Sayer, A. (1984) *Method in Social Science: A Realist Approach*, 2nd edn, London: Routledge, 1992.(A very useful realist textbook on method.)

Schumpeter, J.A. (1954) *History of Economic Analysis*, New York: Oxford University Press.(A rich historical source, but not helpful as regards the *Methodenstreit*.)

Schütz, A. (1966) *The Collected Papers*, 3 vols, The Hague: Niijhoff.(Schütz was central in the effort to restore 'subjectivity' to social scientific understanding - versus the reigning positivism. Difficult.)

Shanley, M.L. and Pateman, C. (eds) (1991) *Feminist Interpretations and Political Theory*, College Park, PA: Pennsylvania State University Press.(An excellent collection of feminist re-examinations of many of the figures discussed in this entry.)

Skinner, Q. (1978) *The Foundations of Modern Political Thought*, 2 vols, Cambridge: Cambridge University Press, 1978.(A detailed study with attention to the development of the concept of the modern state, a datum for all subsequent social scientific thinking.)

Smith, A. (1776) *An Inquiry into the Nature and Causes of the Wealth of Nations*, eds R.H. Campbell, A.S. Skinner and W.B. Todd, Oxford: Clarendon Press, 2 vols, 1976.(A classic, but as much sociological and historical as economic.)

Spencer, H. (1850) *Social Statics*, New York: Appleton, 1897.(Spencer's best effort to defend '*laissez-faire*'.)

Spencer, H. (1862) *First Principles*, Westport, CT: Greenwood Press, 1976.(Aims to show that nature and history may be understood in terms of fundamental, evolutionary principles.)

Vico, G.B. (1725) *The New Science*, trans. T.G. Bergin and M. Fisch, Ithaca, NY: Cornell University Press, 1948. (Usually ignored, Vico's work is strikingly modern in many ways.)

Watkins, J.W.N. (1957) 'Historical Explanation in the Social Sciences', *British Journal for the Philosophy of Science* 8: 104-17.(Perhaps the 'classic' statement of 'methodological individualism'.)

Weber, M. (1903-06) *Roscher and Kneis: The Logical Problems of Historical Economics*, trans. with an intro. by G. Oakes, New York: Free Press, 1975.(This book contains Weber's most systematic effort to think through problems in the philosophy of social science, but it is not often read. Hard going.)

Weber, M. (1904) '"Objectivity" in Social Science', in *The Methodology of the Social Sciences*, trans. E.A. Shils and H.A. Finch, New York: Free Press, 1949.(This volume contains the more famous of Weber's discussions of social science.)

Williams, R. (1977) *Marxism and Literature*, Oxford: Oxford University Press.(A very influential effort to overcome the 'reductionism' of much Marxist theory.)

Social science, methodology of

Each of the sciences, the physical, biological, social and behavioural, have emerged from philosophy in a process that began in the time of Euclid and Plato. These sciences have left a legacy to philosophy of problems that they have been unable to deal with, either as nascent or as mature disciplines. Some of these problems are common to all sciences, some restricted to one of the four general divisions mentioned above, and some of these philosophical problems bear on only one or another of the special sciences.

If the natural sciences have been of concern to philosophers longer than the social sciences, this is simply because the former are older disciplines. It is only in the last century that the social sciences have emerged as distinct subjects in their currently recognizable state. Some of the problems in the philosophy of social science are older than these disciplines, in part because these problems have their origins in nineteenth-century philosophy of history. Of course the full flowering of the philosophy of science dates from the emergence of the logical positivists in the 1920s. Although the logical positivists' philosophy of science has often been accused of being satisfied with a one-sided diet of physics, in fact their interest in the social sciences was at least as great as their interest in physical science. Indeed, as the pre-eminent arena for the application of prescriptions drawn from the study of physics, social science always held a place of special importance for philosophers of science.

Even those who reject the role of prescription from the philosophy of physics, cannot deny the relevance of epistemology and metaphysics for the social sciences. Scientific change may be the result of many factors, only some of them cognitive. However, scientific advance is driven by the interaction of data and theory. Data controls the theories we adopt and the direction in which we refine them. Theory directs and constrains both the sort of experiments that are done to collect data and the apparatus with which they are undertaken: research design is driven by theory, and so is methodological prescription. But what drives research design in disciplines that are only in their infancy, or in which for some other reason, there is a theoretical vacuum? In the absence of theory how does the scientist decide on what the discipline is trying to explain, what its standards of explanatory adequacy are, and what counts as the data that will help decide between theories? In such cases there are only two things scientists have to go on: successful theories and methods in other disciplines which are thought to be relevant to the nascent discipline, and the epistemology and metaphysics which underwrites the relevance of these theories and methods. This makes philosophy of special importance to the social sciences. The role of philosophy in guiding research in a theoretical vacuum makes the most fundamental question of the philosophy of science whether the social sciences can, do, or should employ to a greater or lesser degree the same methods as those of the natural sciences? Note that this question presupposes that we have already accurately identified the methods of natural science. If we have not yet done so, the question becomes largely academic. For many philosophers of social science the question of what the methods of natural science are was long answered by the logical positivist philosophy of physical science. And the increasing adoption of such methods by empirical, mathematical, and experimental social scientists raised a second central question for philosophers: why had these methods so apparently successful in natural science been apparently far less successful when self-consciously adapted to the research agendas of the several social sciences?

One traditional answer begins with the assumption that human behaviour or action and its consequences are simply not amenable to scientific study, because they are the results of free will, or less radically, because the significant kinds or categories into which social events must be classed are unique in a way that makes non-trivial general theories about them impossible. These answers immediately raise some of the most difficult problems of metaphysics and epistemology: the nature of the mind, the thesis of determinism, and the analysis of causation. Even less radical explanations for the differences between social and natural sciences raise these fundamental questions of philosophy.

Once the consensus on the adequacy of a positivist philosophy of natural science gave way in the late 1960s, these central questions of the philosophy of social science became far more difficult ones to answer. Not only was the benchmark of what counts as science lost, but the measure of progress became so obscure that it was no longer uncontroversial to claim that the social sciences' rate of progress was any different from that of natural science.

1 Testability

As in natural science, for a long time one leading aim of many philosophers of social science was to improve and ensure the ‘scientific’ character of theories in social and behavioural science by increasing their testability. The demand for testability was characteristic of logical positivist philosophy of social science. Philosophers like Neurath insisted that much which passes for social science was pseudoscience because there was no empirical evidence which could bear on its truth or falsity (see Positivism in the social sciences §2). Even more vigorously, Karl Popper and his followers long wielded the requirement that scientific theories be in principle falsifiable as a litmus test to find fault with Freudian psychodynamic theory, Marxian economics, and functional sociological theory. Operationalists following Bridgman insisted that for any term introduced in a scientific theory, there be specified operations to tell whether the term applied to something or not (see Operationalism). Empiricist-oriented social scientists, behaviourists in psychology or sociology like B.F. Skinner or G. Homans, neoclassical economists like P. Samuelson, or Milton Friedman, biologically inspired anthropologists like M. Harris, and a whole host of behaviouralists in political science, attempted to reorient theory in order to meet the positivist demand that it be possible to state explicitly what sort of evidence would confirm or disconfirm it (see Behaviourism in the social sciences §§1, 3). One result of the demand for testability was a suspicion of theoretical terms, neologisms, and metaphorical expressions invoked without definitions that could link them to observations providing these terms with empirical content.

Positivism as a philosophy of science receded largely because the positivists and their students were unable to provide an account of empirical testability which satisfied their own standards of adequacy. All specific formulations were found either too narrow - excluding as untestable such scientifically indispensable concepts as ‘positive charge’ or ‘acid’, or too broad - including as testable such pseudoscientific concepts as ‘the absolute’. With no adequate criterion of testability, the demand that theories satisfy strictures on empirical verifiability came gradually to be surrendered in the philosophy of social science. With the surrender of the search for such principles, the inclination to stigmatize some social theories as meaningless declined and the prescriptive role of the philosophy of social science weakened as well. Nevertheless, there remains among some philosophers and many social scientists a healthy suspicion of explanatory terms and theories embodying them, when these theories lack significant predictive power.

Among some social scientists, especially economists, the supposition that there is a test for scientific as opposed to non-scientific discourse or metaphysics or pseudoscience lasted far longer than it did among empiricist philosophers of science. And though the demand for testability may have had a salutary effect on the minimization of cant and circumlocution, it could no more be honoured by significant theory in social science than it could in physics or chemistry. This has made much of the official philosophy of science of disciplines like neoclassical economics particularly schizoid. Among economists Popper’s demand that theory be falsifiable has long held sway in the methodological volumes while being steadily ignored in actual economic theorizing. The demand for falsifiability, like that of testability, has been shown to be a ‘will-o’-the wisp’, in large part because falsifying evidence always impugns a large set of hypotheses, not just the particular one the scientist sets out to test. Falsification casts doubt as well on all the auxiliary hypotheses governing the behaviour of measuring instruments, establishing the character of the boundary or initial conditions under test, and assuring the reliability of the data of a test as a reflection of the phenomena under study.

The failure of various principles of testability to be reflected in the actual scientific practice of economics and other disciplines, increasingly resulted in a greater interest by philosophers in the actual character of theory appraisal as pursued by social scientists in the several sciences than in the methodological expressions of opinion by social scientists. This increased attention to what social scientists do, as opposed to what they say they should do, has characterized post-positivist philosophy of social science.

2 Methodological individualism versus functionalism

The question of what the objects of social theories are emerged from the controversy over testability, but has taken on a life of its own. Even before Durkheim, historians had adverted to groups, institutions, and organizations whose existence and behaviour could not be exhaustively analysed into or explained by appeal to the existence and behaviour of the individual agents who participate in them. From Durkheim onward such hypostasis was based on the explanatory role and apparently autonomous coercive powers such wholes seemed to have (see Holism and individualism in history and social science).

To those who were sceptical about the notion that there were, in Durkheim's terms, social facts above and beyond individual ones, the slogan that the whole is greater than the sum of its parts was simply mystery-mongering provocation. Foremost among social scientific opponents of this holism were the economists, whose own theory rigorously rejected any dispensation from the obligation to explain all economic phenomena by derivation from the rational choices of individual agents. Empiricist philosophers of social science make common cause with such social scientists: since social wholes, facts, institutions, and so on, cannot be directly observed, and since ontologically their existence depends wholly on the existence of agents who compose them, it is tempting to claim that such wholes must be reducible by definition or by explanation to the behaviour of individuals. Allowing such wholes autonomous existence is not only metaphysically bootless, but epistemically gratuitous.

With the demise of demands for testability much of the force of the purely epistemological argument against holism must fade. Thus contemporary debates about methodological individualism versus holism turn on the explanatory indispensability of the appeal to trans-individual entities within social science and biology.

When asking the question 'why biology?' it is important to bear in mind that over the second half of the twentieth century lessons and morals drawn from biology and the philosophy of biology have bulked large in disputes within the philosophy of social science. Just as philosophers have become more interested in the actual practice of social science, so too have they acquired an interest in biology's methodological agenda. The reasons for this interest overlap those of the philosopher of social science. Examination of biological methodology must shed light on the adequacy of a philosophy of science drawn from the examination of physics, and differences between biology and physics will show that prescriptions drawn from physics are inapplicable in biology. This will reinforce the argument that such inapplicability in social science shows the irrelevance of methodological strictures drawn from physical science beyond its official writ. This is a point to which we return below.

Meanwhile, as in social science, evolutionary biology seems to countenance holistic theories, ones which postulate the existence and causal role of family groups, inter-breeding populations, species and ecosystems independent of the individual organisms that compose them. If such postulation is legitimate in biology, the argument proceeds, it should be equally legitimate in social science. On the other hand, some methodological individualists argue the very reverse: first they show that evolutionary explanation in biology is implicitly or explicitly individualist, and then they argue that it must be so in social science as well.

Whether the argument from biology tells in favour of or against the methodological individualist in social science hinges on the correct understanding of teleological explanation and functional analysis in biology. This is another reason why philosophers of social science closely follow or participate in debates among philosophers of biology.

Durkheim was among the earliest explicitly to attribute functions to social institutions above and beyond those individuals ordain or recognize. Durkheim and functionalist social scientists who follow him hold that social wholes exist in order to fulfil certain functions and that the fact that they fulfil such functions can actually explain their existence. Their argument for this view simply followed biological precedent: such explanations are widespread and universally accepted in life science. For example, the presence of the heart is explained by citing its function, the pumping of blood. By contrast the presence of the appendix in humans is problematical, just because it has no function. *Mutatis mutandis* in social theory: social structures exist in order to curb anomie, minimize alienation, optimize social integration, or fulfil some other function vital to the society's survival or well being.

At least since Spinoza philosophers and others have been suspicious of functional and other forms of purposive explanation just because they seem to reverse the order of causation (see Functional explanation; Functionalism in social science). To explain the presence of the heart by appeal to its pumping the blood is to cite an effect to explain its cause. As Spinoza said, this is to reverse the order of nature. Worse, many things with functions do not fulfil their purposes. For instance, most sperm cells fail to fertilize any egg, yet that is their function. Can we explain the presence of a particular sperm cell by adverting to a function it fails to perform? Add to this the difficulty of identifying functions, both in the biological case and the social one: what exactly is the function of the peacock's plumage, or matrilineal marriage rules in a patrilateral society? Many empiricist philosophers of biology have looked to the theory of natural selection to legitimize, eliminate and minimize the ontological excesses of functional explanation in biology, and by parity of reasoning the problematical role of such explanation in social science. The theory of natural selection is sometimes invoked to legitimate functional explanation and sometimes

to show that teleology is a mere appearance - an overlay we place on purely causal processes. Either way the analysis is roughly the same: the appearance or the reality of adaptation is the result of a long and slow process of random variation in hereditary traits subjected to the culling of nature in the struggle for survival. In a relatively constant environment over a long period of successive generations, variants that are fortuitously advantageous will be selected and will increase their proportion in the whole of a population until the variants become ubiquitous. Thus, to say mammals have hearts in order to pump blood is true and explanatory because the heart exists in mammals now as the result of a long process of selection for blood pumps.

Once teleology is legitimated in biology, it is mere cavilling to withhold it from the social sciences. The trouble is that proponents of its legitimacy in social science are obliged to establish close analogies between mechanisms of biological and social evolution. Here the problem for the methodological holist is that functional explanations in biology are widely held to substantiate a version of methodological individualism. By and large there is agreement among evolutionary biologists that selection does not operate at the level of the group, but only at the level of the individual, that the mechanism of hereditary transmission operates exclusively at the level of the individual and that group properties must be fully explained by appeal to the properties and interactions of individuals. Functional explanation in biology seems resolutely individualist.

This result is disturbing for holists. Their best argument for the existence of social wholes and their properties is the explanatory role of social roles and their properties. But these properties - say kinship rules - are usually accorded a functional role, for example, that of enhancing social integration, and their existence is explained by citing these functions. If functions have explanatory force only to the extent that their existence can in turn be given a thoroughly individualist foundation, then for the holist the game is not worth the candle. The best a holist can hope for is that the drift of the debate in the philosophy of biology, which has long favoured the individualist, may turn in the other direction. Short of that, holists have no other recourse but to repudiate the relevance of biology in the justification of social methodology. To do this is of course to surrender ‘naturalism’ - the doctrine that the methods of natural and social sciences should be broadly similar. This is an approach many social scientists have further independent reason to contemplate, as we shall now see.

3 Intentionality laws and the philosophy of psychology

As noted above, perhaps the central questions in the philosophy of social science are whether the social sciences do or should employ the same methods as the natural sciences. The thesis that the social sciences should and can do so is traditionally labelled naturalism (see Naturalism in social science). Its denial has been borne by a succession of movements in social science and its philosophy: structuralism, semiotics, ethnomethodology, hermeneutics, interpretationalism, and more recently deconstruction, postmodernism, and rhetoric (see Post-structuralism in the social sciences §2; Structuralism in social science). These approaches differ from each other in crucial ways. But they share in common a rejection of naturalism.

The issue on which naturalism and anti-naturalism have longest contended is that of the nature of human action and its explanation. All parties agree that social science shares a presumption, along with history and common sense, that much human behaviour - the displacement of the human body - is action, that action is explained by the joint operation of desires and beliefs, and that action and its consequences are the concern of the social sciences. This is a theory which, on the one hand, is so obvious as to go unmentioned in history and biography, and, on the other hand, has been transformed into the economist’s formalization as rational choice theory: each individual has a set of preferences - that is desires - which set is complete, transitive, and continuous, and a set of expectations - beliefs - about available means of satisfying these preferences, and each individual is rational - that is, chooses that action which, in the light of expectations, will attain the object of strongest desire (see Rational choice theory). If explanation of human action is common sense and all the social sciences appeal to this principle, formalized or not, then the vindication of naturalism or its refutation turns on whether some version of the theory of rational choice is a causal law or not. Similarly the adequacy of anti-naturalism hinges on whether such explanations’ force lies in some non-causal power to illuminate their explanans.

This is because scientific explanation is held crucially to involve derivation of the explananda from causal laws and initial or boundary conditions. Though this analysis of explanation in science has been significantly qualified and circumscribed over the years, the notion that explanation involves systematizing laws and/or causality remains a fixed point in the philosophy of natural science. Accordingly, if a principle of rational action is indispensable in

social explanation, then naturalism requires that the principle's explanatory force rests on a causal or nomological understanding. It will have to be a causal law that:

L (x) (if x desires d, and x believes that all things considered doing action a is the most efficient means of attaining desire d, then x does a).

Or if this is not a law, it had better be improvable in the direction of a law of human behaviour. The requirement that a principle of rational choice must be treated as a causal regularity has been common to naturalists in the social sciences at least since it was implicitly embraced by Max Weber. Treating rational choice theory as at least a body of incipient laws is especially crucial to any attempt to make sense of the actual practice of economic theory. Given the predictive weakness of economic theory and its resolute attachment to rational choice theory as its explanatory core, it becomes crucial to economists' claims for their science to show that this core can be retained as a body of laws or approximations to them in the face of apparent empirical disconfirmation.

However the debate on whether a principle like L embodies a law or not is a chapter of what was once the philosophy of mind and has become the philosophy of psychology. For, as Hume long ago noted, for L to be a law, beliefs, desires, and actions must behave in the way that causes and effects recognized in the natural sciences behave. They must be logically independent of one another and it must be possible to establish that each of a particular package of belief, desire and consequent action, obtain without having to establish that the other two obtain. However, the logical connection between these states is something that has long been recognized in the philosophy of psychology. Beliefs and desires have what Brentano unmetaphorically described as 'aboutness', or content or intentionality (see Intentionality §1). Beliefs are about actual or (in the case of false beliefs) non-actual states of the world, as are desires; actions are distinct from mere bodily motion only because they are the effects of desires and beliefs. Thus, action too is imbued with intentionality. Intentionality is an obstacle to a naturalistic treatment of the psychological for two reasons. First, beliefs and desires are identified and distinguished from one another by their intentional content; but the only way to establish the content of a person's beliefs, given their actions, is to have prior knowledge of all their desires and all other beliefs, and vice versa. Moreover, in order to infer desire and belief from action one must be able to distinguish the action which the combination of the desire and belief cause from mere behaviour, and this cannot be done unless we can establish that the body's motion constitutes action - that is movement caused by belief and desire. We are thus caught in an intentional circle. There is no way independent of the effects of action to establish that its causes obtain, and vice versa. But causes and effects must be logically distinguishable from each other; more than that they must be methodologically distinguishable. Otherwise there will be no way to test the claim that some combination of desire and belief causes some particular action, and consequently no way to systematically apply our theory of rational choice in the prediction of actions with any hope of improvement over common sense.

Of course if we could establish when a certain combination of desires and beliefs obtain independent of the actions they cause, for example by reading mental states off from the neurological states of the brain, we could in principle identify causes and effects independently. Alas, philosophers and psychologists from Descartes to Skinner have rejected this course as unavailing either in principle or in practice. Despite the scientific conviction that the mind is the brain, no one has yet overcome Descartes' arguments against this claim, nor shown to general satisfaction how intentional states could be physical states. And even were this obstacle overcome, as Skinner long argued, neuroscience can provide no real help in establishing the boundary conditions to which intentional generalizations like those of rational choice are applied for explanation and prediction.

In the latter half of the twentieth century the philosophy of social science was dominated by the dispute about whether the intentional explanations of common sense, history, cultural anthropology, a good deal of political science and sociology, or their economic and psychological formalization, are or could be causal laws. Naturalists proclaimed that they were, but with the coming of Wittgenstein's influence in the philosophy of mind, this view came increasingly under attack. The gist of this attack on naturalism was that since intentional states and actions are logically connected with one another, explanations that appealed to them could not be causal. Instead the explanatory force of such explanations had to have different non-naturalistic foundations. As Wittgenstein wrote in the *Philosophical Investigations*, 'In psychology there are experimental methods and conceptual confusions' (1953, pt XIV: 2325). The conceptual confusion was to treat belief and desire as the causes of action, and to approach the generalization which links them as an empirical generalization which might be improved and refined

so as to become a law. In fact, beliefs and desires are linked to actions as their reasons, and the linkage is established by rules. It is to this confusion of rules for regularities that the sterility and vacuity of much social science is attributable. Rules are learned by asking the right questions, not by making experimental observations of behaviour. When we attempt to apply empirical methods to what is in essence a conceptual inquiry the result is bound to be unsatisfactory.

Opponents of naturalism before and since Wittgenstein have been animated by the notion that the aims of social science are not causal explanation and improving prediction, but uncovering rules that make social life intelligible to its participants (see Explanation in history and social science). For these purposes there is no alternative to ‘folk psychology’, the account of action and its sources implicit in our every day beliefs and ubiquitous in all cultures. Folk psychology is what enables us to ‘interpret’ the behaviour of others, to show it rational or reasonable by our own lights. If we fail to so understand the actions of others, then by and large the fault is not in our ‘theory’ but in our application of it. We have misdiagnosed the beliefs and the desires of those we seek to understand. From this view the goal of social inquiry is to be understood on the model of the cultural anthropologist ‘going native’ in order to learn the meaning of day-to-day life for the participant of the culture under study (see Anthropology, philosophy of §1). These meanings are embodied in rules. Indeed the principle of rationality is but a rule which may characterize only western culture. Note that rules may be broken, and when they are there are further rules which dictate the sanctions to be imposed, and so forth. The social scientist’s objective is to uncover these rules which render what happens in a society intelligible, though they never make social life predictable beyond limits set by common-sense folk psychology.

That social science is a search for intelligibility will explain why its theories ought not be construed causally and why it neither embodies nor needs explanatory and predictive laws. Thus, the failure of empirically inspired social science to uncover generalizations about human action that seem reasonable candidates for laws or even their rough and improvable precursors is explained not by the complexity of human behaviour and its intentional causes, but by the fact that such a search for laws misunderstands the aim of social science and the role which concepts like rationality sometimes play in attaining this aim. This aim is an interpretation of actions and events which gives them meaning - sometimes the participant’s meaning, sometimes a ‘deeper’ meaning, but always one which presupposes a significant overlap in most of the broader beliefs and desires of the participants and observers as well. However, by adapting the arguments of Quine, anti-naturalists have concluded that the sort of interpretation sought is inevitably underdetermined by the evidence, defeasible, and is a construction subject to negotiation among interested parties.

Under various names this anti-naturalist view of the aims and claims of social science has waxed and waned in fashion along with naturalism from Dilthey and Weber to the present. There is, however, a third alternative to asserting or denying that beliefs and desires work together to explain behaviour as action through causal laws. Eliminativism is an empiricist philosophy of social, behavioural and cognitive science which adopts the interpretationalist conclusion that under their intentional characterizations beliefs and desires cannot be linked to behaviour via laws; so much the worse for beliefs and desires (see Eliminativism). Since our goal in social science is causal explanation and improving precision and scope of prediction, we should surrender any hope of explaining behaviour as action caused by intentionally characterized psychological attitudes. Instead we should adopt a neuroscientific or some other sort of non-intentional perspective on individual behaviour, and we should seek aggregate generalizations about social processes while remaining agnostic as to their psychological foundations.

Eliminativism has found few defenders in either social science or its philosophy. Faced with the Scylla of interpretationalism and the Charybdis of eliminativism, most naturalists among social scientists and philosophers participating in this debate have challenged a presumption shared by both eliminativists and interpretationalists: the claim that on its naturalistic interpretation rational choice theory cannot reasonably be construed as embodying empirical generalizations with any prospect of being improved into causal laws. Instead naturalists point with pride to relatively controversial and certainly limited successes whether in economics or political science or sociology. More to the present point, naturalists dispute the philosophical theses from which the interpretationalist and the eliminativists draw their pessimistic conclusions about the prospect for intentional laws. Some naturalists dispute the requirement that the description of causes be logically distinct from those of their effects. Others argue that despite ineliminable *ceteris paribus* clauses, the status of the rationality principle as a general law is unimpeachable, or at least no more problematical than *ceteris paribus* laws elsewhere, in biology for example.

These philosophers of social science continue to seek the obstacles to predictive power in the social sciences in the complexity and interdependence of human behaviour, and in the openness of social processes to interference by exogenous forces. Others seek the limitations on predictive strength of social science in the reflexivity of social phenomena.

4 Reflexivity and historicism

One set of problems that the social sciences do not share with the natural sciences stem from the fact that the subjects of social science are themselves epistemic agents, that can be influenced by their own beliefs about the generalizations, the input and the output of social theory (see Social science, prediction in). It is well known that the publication of an economic prediction can result in its being falsified by the action of agents who act on the prediction, or again that the publication of polling results can make their predictions self-fulfilling. This fact has led to an entire movement in macroeconomics, 'rational expectations' theory, which accords the subjects of economic theory - individual rational agents - at least as much knowledge of economic theory as it accords government policy makers. Under this assumption it can be shown that implementing certain policies predicated on the truth of Keynesian theory will cause that theory to be falsified.

Theories and predictions whose dissemination can effect their confirmation are known as 'reflexive' ones. Some philosophers and social scientists have held that theories in social science must be different in kind from those of natural science because the former are potentially reflexive when the latter are not. One extreme version of this view denies that social theory can improve prediction beyond certain narrow limits, and so constitutes a serious obstacle to a naturalistic social science uncovering a succession of improvable causal generalizations. Among advocates of critical theory the doctrine is held not so much to limit knowledge, but to burden it with a special responsibility. Critical theorists hold that since theory can influence social behaviour it ought to, or at least the social scientist has the responsibility of framing and disseminating theory in a way that will emancipate people by showing them the real meaning of social institutions and freeing them from false and enslaving beliefs about themselves and their communities (see Critical theory). Critical theorists adopt an empiricist account of natural science, but they insist that the reflexive character and normative aims of social science make for important differences in its methods and epistemology: social science is a search for emancipative intelligibility, not laws, or even rules. Its methods are social criticism of ideologies masquerading as fixed truths, mere interpretations which are to be unmasked as social constructs, not the inevitable result of natural forces.

As critical theory and other anti-naturalistic doctrines give way to more radical doctrines, even its concessions to the empirical character of natural science are withdrawn, in favour of an inference from the non-empirical character of social science to the ideological, negotiated non-cumulative character of natural science. Postmodernism, helping itself to a radical interpretation of Kuhn's theory of scientific change, not only denies that the social sciences have a methodology or an epistemology, but also that natural science yields objective information about the way the world or even observable phenomena are.

These more extreme anti-naturalistic doctrines share with nineteenth-century philosophy of history a commitment to 'historicism' (see Historicism). The natural sciences have traditionally been viewed as ahistorical in a number of different senses. Natural laws are typically time symmetrical: given laws and initial conditions for a closed deterministic system, we can retrodict past events as well as future ones. There is no causal action at a temporal distance: a past event can only influence a future one transitively through their intermediate effects at each intervening event between the cause and its ultimate effect. If there are causal laws their writ runs across all places and all times: a regularity confirmed in one spatio-temporal region and disconfirmed in another is not a law in either region, it is at best a local empirical regularity to be explained by some exceptionless universal law.

Historicism in social science involves the denial that one or another of these three theses characterizes the social sciences. Typically historicists argue that social processes reflect the operation of asymmetrical principles which mandate a fixed order of events: thus capitalism could not have come into existence without the prior appearance of feudalism; and adult neurosis could not have come into existence without the prior frustration of infantile sexuality. Historicism sometimes also embodies the thesis that each historical epoch operates in accordance with its own distinct explanatory laws, and that sometimes the discovery of such laws can usher in a new era with new laws - whence the connection between historicism and reflexivity.

Reflexivity raises important methodological questions: Can we minimize the obstacles to empirical testing that self-fulfilling prophesies and suicidal predictions make? If not, how do we assess the cognitive status of explanations embodying reflexive theories? Historicism raises metaphysical questions of an even more fundamental sort: Suppose historicism is true, what is it about human action, social institutions, and large scale historical events that makes them so different from causal processes governed by symmetrical causal laws, and how can events reach out to produce much later ones without going through normal causal chains? These questions either go unanswered in contemporary debates or lead us back to problems about the intersection of the philosophy of social science and the philosophy of psychology: problems about the nature of intentionality and the mind. For the answers given to these questions about the historical character of social inquiry invariably appeal to agency, action, will and thought.

5 Facts, values and dangerous knowledge

One traditional set of questions distinctive of the social sciences reflects their special relevance to normative questions about individual and social policy (see Value judgments in social science). Well confirmed theories of human behaviour provide the means to ameliorate, or to worsen human life. This fact raises questions about how this knowledge should be employed. In addition, in choosing which research questions to examine, and which hypotheses to test, the social scientist makes value judgments about the interest, importance, significance of alternatives. However these questions are in principle no different from those raised by advances in theoretical physics. Different questions are raised by the fact that well-confirmed social theories would enable us to control and manipulate individual and aggregate human behaviour. A further distinctive problem is raised by the need to employ human subjects in order to test some theories of human behaviour. Whether it is permissible to treat humans in the way we treat laboratory animals, or even animals in field studies, is an issue social scientists face along with medical researchers.

Additionally, there is the problem of potentially dangerous knowledge. Some inquiries are best left unmade, or so it is alleged. Studies of the correlation of criminality and chromosomal abnormality, or the heritability of intelligence, or the dynamics of jury deliberation, will be condemned on the ground that disseminating the findings may be harmful whether they are scientifically significant or not. Over the last half century this claim has been made with special force in regard to studies of the statistical heritability of IQ among various groups. Some philosophers have attacked such studies on cognitive grounds, arguing that IQ is not a measure of intelligence, and that heritability shows little about genetic inheritance. They have also held that the examination of such questions should be forsworn because merely pursuing them is socially inflammatory and the results, even of well-conceived and well-executed studies, are likely to be misused. Whether this prospect raises special questions beyond those faced in research on toxic chemical substances or harmful disease vectors that might be inadvertently released is one the philosopher of social science needs to debate.

Beyond the normative issues to which social science is relevant, there is the further debate among philosophers of social science about whether claims in the social sciences are themselves explicitly, implicitly, inevitably evaluative, normative, prescriptive, or otherwise ‘value laden’. Arguments for this claim often turn on the allegedly evaluative meaning of certain descriptive and explanatory concepts indispensable to varying social theories. For example, the term ‘rational’ has positive connotations, as do expressions like ‘functional’, or ‘adaptational’. No matter what meaning is stipulated for these terms they may nevertheless convey attitudes or obstruct certain questions without the social scientist recognizing their normative role. More fundamentally, the very treatment by social science of institutions and norms as subjects of objective scientific exploration may unwittingly suggest the naturalness, inevitability and immutability of social arrangements which are in fact artificial, constructed and subject to negotiation. As noted above, it is the responsibility, some will hold, of social scientists to unmask the character of oppressive or exploitative institutions; this is made more difficult by the failure to recognize the implicit normative dimension of social theories and methods.

On a traditional view of the normative dimension of social science *qua* science there is a distinction between facts and values, and by scrupulousness about this distinction the social scientist *qua* scientist can and should avoid making normative claims implicitly or explicitly. The normative force of this claim rests on the view that scientists should be as objective as possible. For the value of scientific knowledge and its further accumulation is jeopardized by the appearance of partiality. Radically opposed to this view is the claim that objectivity is

impossible in any science, social or natural, that ‘knowledge’ is a coercive term that obscures the partiality and negotiated social constructions of physical science, and in any case, as Kuhn is taken to have shown, there is no real accumulation or progress in the history of science. Ironically, on this radical view, the problem of normative versus positive theory is not at all a distinctive one for the philosophy of social science. Either it is a problem for the philosophy of all the sciences or for none of them.

Social sciences, philosophy of

Although some of the topics and issues treated in the philosophy of social science are as old as philosophy itself (for example, the contrast between nature and convention and the idea of rationality are dealt with by Aristotle), the explicit emergence of a subdiscipline of philosophy with this name is a very recent phenomenon, which in turn may itself have stimulated greater philosophical activity in the area. Clearly, this emergence is tied to the development and growth of the social sciences themselves.

1 Historical approach

There are, perhaps, four distinct ways in which to gain an understanding of the subdiscipline. These ways are, of course, complementary. First, just as with most other areas of philosophy, one might approach the philosophy of the social sciences historically, by studying major schools or philosophers of an earlier period. There is much to recommend this approach (see Social science, history of philosophy of). There are a number of classical texts (by Weber and Durkheim, for example) of which any interested student of the philosophy of the social sciences should be aware, much as there is in epistemology or ethics. This provides an interesting contrast with the philosophy of the natural sciences; far less could be said in favour of gaining an understanding of the latter in this way.

Compared with other areas of philosophy, the history of the philosophy of the social sciences is somewhat truncated, since it can only begin properly with the earliest attempts at social science, in the late eighteenth and early nineteenth centuries, first in the Scottish Enlightenment and subsequently in Germany. Prior to this period, there had been speculation about the nature of society, some of it quite rich and rewarding (Hobbes and Vico provide two examples of this), but it is only in the period of the Scottish Enlightenment and after that writers begin to reflect the first systematic attempts to study and understand society.

There is no clear line of demarcation between philosophers of social science and of society on the one hand and social theorists on the other, especially in this early period. Conventionally, to select only a few examples, G.W.F. Hegel, Wilhelm Dilthey, F.H. Bradley and T.H. Green are considered to be examples of the former, and Adam Smith, Karl Marx, Émile Durkheim, and Max Weber, are considered as examples of the latter, but the line is sometimes somewhat arbitrary (see Hegel, G.W.F.; Marx, K.; Dilthey, W.; Bradley, F.H.; Green, T.H.; Smith, A.; Durkheim, É.; Weber, M.).

2 Problems

A second way in which to gain an understanding of the philosophy of social science is through the study of the issues and problems that these writers, and their contemporary counterparts, address (see Social science, methodology of). Many of these problems arise in ordinary as well as in more scientific discussions of and thought about the social realm. It is not only social scientists who think about the social world; all of us do, a great deal of the time. Even in those cases in which the social scientist introduces neologisms, for example, ‘demand curves’ or ‘anomie’, they seem closely connected to, and sometimes only a refinement of, concepts already grasped by the lay person.

This nonscientific reflection arises quite apart from any specialized scientific work. It is, to a certain extent, misleading to think of the field as only the philosophy of the social *sciences*. Since so much of the motivation for critical discussion of the problems in this area comes from philosophical reflection on these quite ordinary modes of thought and understanding, the field should perhaps be called ‘the philosophy of *society*’, to reflect this nonscientific, as well as the scientific, interest in those problems.

Most of the things that social science is about, social structures (like families or society itself), norms and rules of behaviour, conventions, specific sorts of human action, and so on, are items that find a place in the discourse of the ordinary lay person who has as good a grasp of common talk about social class and purchase, voting and banking, as does the social scientist. This raises, in a direct way, metaphysical questions about the nature of these things. Are these social structures anything more than just individuals and their interrelations? Many philosophers, in the grip of the ideal of the unity of science, have held out the prospect that social science can be derived from, and is therefore reducible to, psychology (the latter eventually being reducible to chemistry and physics). For such thinkers, the world is ultimately a simple place, with only many different ways in which to speak about it. Other

thinkers have been struck by the reality and integrity of the social world, and how it seems to impress itself on the individual willy-nilly (see Society, concept of; Social norms; Holism and individualism in history and social science).

What is an action, and how does it differ from the mere movement of one's body? It seems hard to say in what this difference consists in a way that remains plausible and true to what action is like. Whatever an action is, what makes some actions *social* actions? One might think that an action is social in virtue of its causal consequences on others. Another line of thought holds that an action is social in virtue of its intrinsic character, quite apart from the question of its effects. Much of the philosophical discussion of action arose in the philosophy of history, over the explanation of historically important action, but has now been absorbed into a separate area of philosophy, the theory of action (see History, philosophy of; Action; Social action).

The alleged contrast between nature and convention occurs to those who think about humankind and its development, whether they be scientists and philosophers or not. Anyone who has travelled widely and noticed the social differences between peoples and cultures may have wondered whether all social practice was rational in its own terms, wherever found and no matter how apparently peculiar by our home-grown lights. Or perhaps, on the other hand, there are some universal standards of rationality, in the light of which evaluation of social practices and criticism of some of them can be mounted (see Nature and convention; Rationality and cultural relativism; Social relativism).

The relationship between scientific theory and ordinary modes of thought is, of course, interactive, since many of the concepts or issues that have become part of ordinary lore have their roots in earlier scientific theory (our modern, and by most accounts, confused, concept of race might be an example of this; see Race, theories of).

Another set of problems arise in thinking through the nature of the social scientific enterprise itself. What standards must full explanation in social science meet? Causal explanation is a mode of explanation in natural science that is, relatively speaking, well understood. Explanations of a ritual or practice in society do not appear to be causal explanations, nor do explanations of human action. The first are often functional explanations (for example, a certain ritual exists because it produces such-and-such) and this appears to be an explanation of something by its effects rather than by its causes. Explanations of human action are intentional explanations, whereby an action is explained by the goal or end at which it is directed. This also appears not to be causal. But perhaps appearances are deceptive, and these can be recast as causal explanations after all (see Explanation in history and social science; Functionalism in social science).

Natural scientists believe that their work is ethically neutral. To be sure, their work can be put to good and bad uses, but this presumably reflects on the users rather than on the content of the science itself. The relationship between social science and the values of the social scientist seems far more immediate and direct than this, and this alleged contrast has been the subject for continuing discussion and debate (see Value judgments in social science).

Is social science like natural science in important ways? In the developed natural sciences, there are controlled experiments and predictions. Neither seem available to the social scientist. Natural scientists attempt to formulate the laws that govern the phenomena they study. Is this a reasonable goal for the social scientist? Certainly, there are not many candidate laws for the social sciences one can think of. Does the social scientist use statistical evidence in the same way as the natural scientist? (See Experiments in social science; Social science, prediction in; Social laws; Statistics and social science.) Finally, in natural science, we distinguish between theory and observation in a relatively sharp way, and we believe that a rational person should accept that theory which is best confirmed by observations. It is not clear that we can make the same distinction in the social sciences, nor that theory is supported by observation in just the same way. Our observations of the social world seem even more coloured by the theory we employ than is the case in the natural sciences (see Theory and observation in social sciences.)

3 Contemporary movements

A third way in which to approach the subject is through the study of either contemporary movements and schools of philosophy, or specific philosophers, who bring a specific slant to the subdiscipline. Controversy marks the natural as well as the social sciences, but observers have noted that there seems to be even less consensus, even less of an agreed paradigm at any particular time, in the latter than in the former.

Critical reflection on society, or on social science, or both, is very different in France and Germany from the way it is in the English-speaking world. The problems are the same, but the traditions and the manner in which the discussions proceed are markedly distinctive. The hope is that each tradition may learn something from the other (see Social science, contemporary philosophy of; Behaviourism in the social sciences; Critical realism; Evolutionary theory and social science; Lévi-Strauss, C.; Naturalism in social science; Positivism in the social sciences; Post-structuralism in the social sciences; Scientific realism and social science; Sociology of knowledge; Structuralism in social science; Symbolic interactionism; Systems theory in social science; Bourdieu, P.; MacIntyre, A.; Schütz, A.).

4 Specific social sciences

Fourth and finally, one might approach the philosophy of the social sciences by studying the philosophical problems that arise specifically within each of the social sciences. Some, although not all, of the social sciences have thrown up philosophical industries all their own. Economics is the most salient example. In many ways, it is the most developed of all the social sciences, and this may be the reason why some of the best-defined controversies in the philosophy of social science arise from within it. Questions about the philosophical foundations of economics touch on the philosophically central issues of rationality, choice and the nature of wants or desires and their connection with action (see Economics, philosophy of; Social choice; Rational choice theory). But other social sciences have also given rise to specific problems, including history, psychology, sociology, and anthropology (see Psychology, theories of; Sociology, theories of; Anthropology, philosophy of).

Social sciences, prediction in

Prediction is important in science for two reasons. First human beings have a practical interest in knowing the future. Therefore, all science is potentially predictive in the sense that its results may be used as a basis for expectations. Second, a test of our beliefs is the truth of the predictions we can derive from them. In the social sciences, however, predictions are often supposed to create specific philosophical and methodological problems, the roots of which are the following: the phenomena studied in the social sciences are so complex and so interrelated that it is practically impossible to formulate law-like generalizations about them; human beings are supposed to possess free will; and the predictions may themselves modify the phenomena predicted.

Some phenomena are deterministic; they obey invariable laws. Some other phenomena are stochastic; they obey laws that could be expressed only in statistical terms. Finally, some phenomena - most notably human actions - are claimed to be free. According to the incompatibilist philosophers, free actions are not subjects of either deterministic or stochastic laws (see Free will §2).

As regards predictability, we should note that (1) predictability does not imply determinism, because we may have statistical predictions concerning stochastic phenomena. (2) nor does determinism imply predictability, for the following reasons: some phenomena are deterministic but chaotic in the sense that changes which are undetectably small can sometimes produce large changes; some phenomena are so complex that it is humanly impossible to describe all the relations and interrelations relevant for predictions; and in some cases it is practically impossible to acquire the information relevant for making informed predictions. From (2) it follows that unpredictability does not imply freedom. All the limitations mentioned in (2) may be relevant in regard to the study of social phenomena. But they can also be relevant in other areas. For example, financial markets may function chaotically, but the same is true of meteorological phenomena. Individual human beings, as well as human societies, are extremely complex entities, but so are animals. Moreover, it is possible for phenomena having extremely complex internal structures to exhibit a predictable pattern in their general behaviour. We may be able to predict the movements of the whole without being able to describe or predict the movements of the parts. Some philosophers have claimed that we cannot find general laws of human societies because all societies are essentially open systems. Unlike in a laboratory experiment, or an astronomical observation, we cannot eliminate the possible influence of outside factors. Thus, we are never entitled to say that phenomena are caused by those particular factors we are experimenting with. Again, all this is equally true in many natural sciences (for example, in meteorology).

It seems that the only philosophical problem specifically relevant to social predictions is the question of free will. However, this supposed freedom does not prevent us making predictions in our everyday life. Usually, we predict without the help of any (systematic) scientific knowledge: we ascribe certain aims and beliefs to our fellow beings, derive rough predictions of how they are going to behave, and form our own expectations accordingly. Similarly, social scientists may postulate general motives, for example, profit maximization, and shared beliefs, for example, correct beliefs about present market prices, deriving useful predictions regarding general trends. Even if the postulates are not true in respect of every individual, individual idiosyncrasies may cancel each other out, or, in particular contexts, there may be pressures among individuals to conform to the postulates. For example, entrepreneurs who do not try to maximize their profits and to use adequate information are soon out of business. The structure of the choice situation may create a predictable pattern.

There is, however, one further problem peculiar to the social sciences only. Mutually held expectations are essential for our social life. Most institutions can work effectively only because people conform to certain predictable patterns, and they conform to these patterns partly because they expect that institutions (for example, banks, governments or courts) will work effectively. When forming expectations, human beings try to take into account information concerning the future, including the information produced by the social sciences. Thus, predictions about the future rate of inflation affect the actual rate of inflation by influencing the expectations of firms and trade unions. Social predictions may possess a self-modifying (reflexive) force: they may make themselves true or untrue. Social scientists may try to take into account the possible effect of their predictions, but the subjects of the predictions may, in turn, react to such attempts. It appears that in certain circumstances a social

theory cannot describe and predict the consequences it has for the people it describes and predicts. This result does not presuppose a metaphysical notion of free will. People may react to the content of a theory T1 in a deterministic way, and this deterministic process can be predicted by another theory T2. T2 cannot predict its own effects, but they can be predicted by T3, and so on.

In some research contexts, the self-modifying potential of predictions can be ignored. First, some issues studied, for example, in psychology, are not really of a social nature. They are closely related to the physiological processes of human beings, setting the necessary conditions and limitations of human agency.

Second, in many cases the predictions produced by social scientists are not available or comprehensible to the subjects of the predictions, for various reasons. This solves the reflexivity problem, but only at an ethical cost. For it means that in such contexts, successful predictions presuppose an informationally superior position.

Third, the predicted social situation may be moving towards a unique equilibrium. Here, equilibrium is a technical notion, meaning that the relevant actors (individuals, firms, states and so on) do not simultaneously possess motive and ability to deviate from the predicted pattern. No new information can change the outcome. In a trivial case (for example, an idealized market situation), all or most agents have only a single feasible option.

The self-modifying effect is likely to appear in situations where no equilibria exist, or where there are several - for example, in imperfect markets, in multiparty politics and in multipolar international systems. In such contexts, the agents have an on-going motive to acquire information and to try to outguess each other’s future actions. Hence, the ability of the social sciences to predict is dependent on the distribution of knowledge in societies.

Social theory and law

Social theory embodies the claim that philosophical analyses, reflections on specific historical experience and systematic empirical observations of social conditions may be combined to construct theoretical explanations of the nature of society - that is, of patterned human social association in general and of the conditions that make this association possible and define its typical character. Social theory, in this sense, can be defined broadly as theory seeking to explain systematically the structure and organization of society and the general conditions of social order or stability and of social change. Since law as a system of ideas can also be thought of as purporting to specify, reflect and systematize fundamental normative structures of society, it has appeared as both a focus of interest for social theory and, in some sense, a source of competition with social theory in explaining the character of social existence.

The relation of legal thought to social theory is, thus, in important respects, a confrontation between competing general modes of understanding social relationships and the conditions of social order. In one sense, this confrontation is as old as philosophy itself. But as an element in modern philosophical consciousness it represents a gradual working-out in Western thought, over the past two centuries, of the implications of various 'scientific' modes of interpreting social experience, all in one way or another the legacy of Enlightenment ideas.

From the late eighteenth century and throughout the nineteenth century, criteria of 'scientific' rationality were carried into the interpretation of social phenomena through the development of social theory. These criteria also significantly influenced the development of modern legal thought. The classic social theory of the late nineteenth and early twentieth centuries, which established an enduring vocabulary of concepts for the interpretation of social phenomena, treated law as an object of social inquiry within its scope. It sought scientific understanding of the nature of legal phenomena in terms of broad systems of explanation of the general nature of social relationships, structures and institutions.

In the late twentieth century the relationship between social theory and law has been marked by fundamental changes both in the outlook of social theory and in forms of contemporary regulation. On the one hand, social theory has been subjected to wide-ranging challenges to its modern scientific pretensions. It has had to respond to scepticism about claims that social life can usefully be analysed in terms of historical laws, or authoritatively interpreted and explained in terms of founding theoretical principles. On the other hand, the inexorable expansion of Western law's regulatory scope and detail appears, sociologically, as largely uncontrollable by moral systems and relatively unguided by philosophical principles. Hence, in some postmodern interpretations, contemporary law is presented as a system of knowledge and interpretation of social life of great importance, yet one that has ultimately evaded the Enlightenment ambition systematically to impose reason and principle - codified by theory - on agencies of political and social power.

1 Civil society and modernity

Social theory aims to develop systematic theoretical understandings of the nature of social phenomena or of 'society' treated as a specific object or focus of inquiry. Intellectual sources of social theory are found in speculations throughout the history of philosophy on the foundations of social order, the character of human association and the essence of human nature. Nevertheless, social theory as a distinct intellectual enterprise is best understood as originating with the Enlightenment. Emerging out of social philosophy, its concerns are closely implicated with general philosophical issues of individuality, rights, authority, responsibility and community. Its establishment as an intellectual field depended on three main developments: first, the identification of an analytically distinct field of the 'social'; second, the acceptance of the necessity of a grounding for social speculation in evidence about social experience in specific historical contexts; and, third, a conception of social change as theoretically explicable, suggesting a qualitative differentiation between 'modern' and 'pre-modern' societies or characteristics of social life.

The identification of a distinct field of the 'social' is associated with the conceptualization, especially derived from Hegelian thought, of civil society as an autonomous realm of social interaction, differentiation, organization and institutions. One consequence of this conceptualization was to identify such institutions as contract, property and social class and the processes and effects of the administration of civil justice as foci for theoretical analysis, not in

terms of their ethical implications or their significance for political theory but as components of a cohesive social fabric requiring explanation in terms of its integrative structure and historical dynamics.

The specification of the ‘social’ also entailed the development of distinctive approaches to analysis and, eventually, the establishment of an intellectual enterprise of sociology claiming its own theory, methods and aims. Beginnings of these processes can be seen in Montesquieu’s *L’Esprit des lois (The Spirit of the Laws)* (1748) which attempts to link typical social and political structures with characteristics of the types of natural and historical environments in which these structures emerge. Climate, geography and population size are related to law and political institutions, and law is seen as a consequence of natural conditions and the culture they inspire as well as a force acting upon them (see Montesquieu, C. §3).

A further element essential to the project of social theory but not present in Montesquieu is a conception of modernity; that is, a conception of a general historical transition from characteristic earlier forms of society or of social relationships to a specifically modern form, which could be generalized as both qualitatively distinct from earlier forms and also typical of the most advanced or developed actual societies of the present. The theme of such a transition pervades the major literature of nineteenth-century social theory. One of its most striking expressions is Ferdinand Tönnies’ distinction (1887) between *Gemeinschaft* and *Gesellschaft*; that is, between, on the one hand, multi-faceted, long-term, often emotionally or traditionally sanctioned social relationships typical of close-knit community or family life and, on the other hand, instrumental, specific and limited, often short-term and frequently changing social relationships based on agreement or the negotiation of rapidly changing patterns of social interaction. Tönnies’ concepts abstractly present ubiquitous elements of social relationships unrelated to any particular historical context, but the inspiration for their formulation was undoubtedly a sense of the increasing prominence of *Gesellschaft* relations in the conditions of mobile, diverse and dynamic ‘modern’ society.

Modernity is characterized variously in the most prominent forms of social theory developed by the end of the nineteenth century: for example, in Herbert Spencer’s emphasis on functional differentiation and reintegration in modern society; in Émile Durkheim’s characterization of complex industrial societies as morally diverse yet also morally integrated by functional interdependence; in Karl Marx’s identification of the anatomy and pathology of capitalist society as a distinct historical form; and in Max Weber’s ambivalent exploration of the progress of numerous forms of rationalization culminating in the bureaucratized technical consciousness and morally compartmentalized social environments of late nineteenth-century Western capitalist societies.

Many of these presentations of modernity in social theory rely on analyses of law and legal history. Law’s doctrinal history provided documentary materials that could be treated as empirical sources in plotting trajectories of social change. Both Tönnies and Durkheim used legal materials - including the jurist Henry Maine’s evolutionary legal history (see Jurisprudence, historical §2) - extensively in developing their accounts of the contrast between social modernity and pre-modernity. And Weber’s discussion of political and economic structures and modes of thought characteristic of developed capitalism is strongly flavoured by his sophisticated understanding of the nature of modern Western legal thought.

2 Science of law and science of society

A further condition for the emergence of social theory was an emphasis on the need for systematic empirical inquiry about social phenomena and an explicit conception of the nature of scientific method in social analysis (see Social sciences, philosophy of §1; Positivism in the social sciences §2). Here it is important to see both a parallel with developing ideas in legal analysis and a challenge to those ideas. Long before the idea of a rational ‘science of society’ began to establish itself (especially through the writings of Henri de Saint-Simon and Auguste Comte early in the nineteenth century), legal thought presented itself as a professional ‘artificial reason’ authoritatively conceptualizing social reality. English common law thought, as elaborated by such as Edward Coke and Matthew Hale in the seventeenth century, embodies conceptions of community that underlie legal doctrine’s interpretations of the normative structure of society.

Late eighteenth-century and nineteenth-century movements for scientific rationalism in legal thought did not necessarily suggest the need for theory that would locate law in a wider terrain of empirical social knowledge. The initial demand was, at least in the English context, for more systematic conceptual analysis of legal doctrine than that allowed by the pragmatic methods of judge-made common law. Nevertheless, utilitarian reformers demanded

that romantic or mythical common law conceptions of community and of an ancient unchanging constitutional order be replaced with more realistic understandings of the nature of modern government, of the sources of legal authority and of the political processes of creation and application of law.

Comte's identification of a specific science of society, which in 1838 he named sociology, is almost contemporaneous with the jurist John Austin's powerfully influential outline of a modern 'science of law', requiring no support from the moralistic speculations of natural law theory (see Austin, J.). The appeal to 'science' made by many nineteenth-century jurists was usually to some general model of rigorous, rational, objective and systematic thought, such as geometry. The contribution of an emerging social theory, during the nineteenth century, was to help bring into legal analysis a self-consciousness about empirical resources for legal speculation and, eventually, a limited recognition that many resources necessary to an adequate theoretical understanding of law must be found, beyond the scope of the lawyer's traditional structures of reason, in systematically ordered data derived from the observation and recording of social experience.

Social theory in the late nineteenth and twentieth centuries shows an increasing attention to the dilemma of the meaning of 'science' in social analysis. The Durkheimian injunction at the end of the nineteenth century to treat social facts as if they were things (objects of science) to be analysed by means of the observational techniques of natural science (see Durkheim, É. §2) was confronted and challenged by contemporaneous claims that the methods of the natural and the social sciences are necessarily radically opposed and that the latter require distinctive methods of interpreting the subjective meaning of social acts for those involved in them if the patterns of social life are to be intelligible to the scientist (see Weber, M. §3).

The often-quoted dictum that sociology was born in a state of hostility to law can be understood as a recognition that in establishing its empirically-oriented, systematic, generalizing modes of analysis of social life, social theory challenged the prerogatives of such established enterprises of social interpretation as those of law. It sought to replace the normative, evaluative social interpretations that legal analysis offered with explanatory, descriptive and ostensibly non-judgmental analyses of social phenomena, including legal phenomena.

In so far as social theory founded itself on conceptions of modernity and sought to explain patterns of social development theoretically, it challenged common law assumptions about the timeless stability of the community whose immanent normative framework the common lawyers purported to understand and interpret. And, in its unending questioning of the nature of 'science' in social analysis, social theory provided material that would eventually challenge lawyers' claims to possess a secure and autonomous 'science of law'. As long as law was admitted to be a social phenomenon, legal theory would eventually have to take account of debates on social interpretation and analysis that social theory presented. In this way, the advent of modernity in law and in social theory raised the possibility that legal science would become dependent on and subordinate to social theory.

3 Law in classic social theory

The bodies of social theory that have exerted most long-term and widespread influence in social analysis and still provide the main vocabulary of concepts for considering the social character of modern Western law are the systems of thought associated with Karl Marx, Émile Durkheim and Max Weber (see Marxism, Western). Their contribution to legal scholarship is especially significant because each devotes considerable attention to law within a wider project of social theory, and because each views law, at least in part, as comprising distinctive systems of doctrine or modes of reasoning. They thus indicate the prospect of directly confronting, in social theory, juristic understandings of the nature and significance of legal doctrine.

In these respects, the contributions of this classic social theory to legal scholarship are broader than is suggested by its use in much of the research in sociology of law. Empirical sociology of law is often behaviourally oriented (focusing on the explanation of activity in legal settings - for example, police practices - rather than on legal discourse or doctrine itself). It tends to be strongly influenced by the present organization of social science disciplines and therefore to reflect their perspectives. Partly as a consequence of this organization which largely excludes law, treating it as an independent and external discipline, sociology of law is often viewed as peripheral by the social science disciplines (especially academic sociology and anthropology) to which it relates. At the same time, sociology of law's respect for disciplinary boundaries of academic social science has often deterred it from engaging effectively with the disciplinary outlook of lawyers and the concerns of legal philosophy.

Marxist theory's main influence on legal analysis has been to highlight the need to relate legal doctrine and legal thought systematically to specific social interests which law promotes and to see law as a focus of political struggle often obscured by the technicality of professional legal discourse. While the link between law and social class interests was recognized long before Marx wrote, Marxist theory has focused attention on the devices by which law's class character may be obscured. It radically challenges the idea that law can attain a level of principled generality that gives it a moral and political autonomy above the endless struggle and compromise of conflicting economic and social interests. Marxist theory does not generally engage with the arguments over legal principle and legal foundations that legal philosophy pursues. Rather it regards legal philosophy's moral arguments as being largely conducted on the terrain of ideology. Marxist social theory's most important contribution to legal analysis is the effort to develop a coherent theory of the nature of ideology; a theory that can be used consistently to relate patterns of legal ideas to broader social, economic and political developments while also explaining the mechanisms and conditions under which legal discourse in advanced capitalist societies consistently proclaims its own moral, intellectual and political autonomy from the conflicting social forces that it purports to regulate.

By contrast, Weber, trained in law and viewing his legal studies as central to his overall project of interpreting the social character of Western capitalism, emphasized aspects of modern law different from the mystificatory or ideological elements and repressive structures that Marx had treated as essential. For Weber, modern law's importance lies primarily in its distinctive forms of rationality, which correspond to certain rational requirements of modern Western state structures. This rationality also underpins forms of purposive social action which are especially highly developed in and important to modern capitalist societies, and it contributes to the stability and legitimacy of modern political systems. Weber's acute sensitivity to changing forms of legal reasoning and decision-making allows him to provide important insights into the social and political conditions of existence of the *Rechtsstaat* (see Rule of law (Rechtsstaat) §1). Unlike Marx, who views legal ideas consistently from the external standpoint of a demystifier and critic of ideology, Weber interprets these ideas in lawyers' terms, understanding both their social importance and the technical processes by which they evolve. Yet he contextualizes this interpretation, explaining, for example, intimate relationships between changing forms of legal reasoning and conditions for the expansion of capitalistic economic activity; and between these legal forms and the kinds of legitimacy claims that political and other authorities are able to make in specific historical conditions.

Because Weber's social theory is informed by a deeper understanding of the technicalities of legal thought than is Marx's, it offers a more nuanced view of the ambiguities of legal modernity. Its complexity of outlook and its ambivalence about modernity in general, and about the rationalization processes at work in modern law, also make the consequences of Weberian social theory for legal philosophy's concerns harder to define than is the case with Marxist theory. In general, despite its richness and a large secondary literature on its legal aspects, Weber's work still remains insufficiently assimilated in legal scholarship. The explanation lies partly in his methods, which reject the possibility of discovering scientific laws in history and celebrate in often dense, much-qualified argument the variety of perspectives that can be brought to light by using provisional, pragmatically chosen interpretive concepts. Beyond this, however, Weber poses profound challenges - rather like Maine in an earlier era - to the jurist to ignore disciplinary demarcations and recognize law's place as one strand of understandings in a vast, complex, cultural matrix of values and beliefs, modes of reasoning and interpretation.

Among the classic social theorists of law, Durkheim has so far exerted least direct influence on legal theory, perhaps because the emphasis of his legal thought, with its almost complete silence on questions about the relations of law and power (social, economic or political), has seemed naïve to legal scholars who absorbed some of the claims of Marx or Weber about the political or economic conditions of existence of law. The emphasis of Durkheim's legal theory is on law's intimate relations with morality and on the problem of defining the moral foundations of law in modern, secular, functionally and socially differentiated societies. In these societies, shared values, if they can be held to exist, are necessarily greatly limited in scope and significance by comparison with the situation in simpler, more socially uniform and close-knit societies, or those where strong and universal religious commitment underpins unifying social values.

Law was an important focus of study for Durkheim and his school of associates but the more limited impact of his ideas on legal theory by comparison with those of Marx and Weber is understandable in so far as the Durkheimian approach seemed to deny what legal scholars, no less than social analysts, came to sense as one of the major

characteristics of modernity - the disintegration of moral unities and the emergence of law as a mechanism by which modern society might endlessly remake itself. The Durkheimian idea of law as a reflection of moral conditions has seemed less appropriate than Marxist and Weberian perceptions of law as a shifting element in complex articulations of economic and political interests in rapidly changing modern society. It has generally seemed more useful to view law as an instrument of political action and a system of ideas integrated with dynamic social forces determining the pace and direction of change and the conditions of social stability.

4 Law and recent social theory

During the last decades of the twentieth century, social theory increasingly rejected or radically modified the three assumptions or claims - a distinct realm of the 'social', distinctive 'scientific' methods of analysis of social phenomena, and the experience of modernity as the ever-present context of analysis - underpinning its original development. This phase of the relationship between social theory and Western legal thought is characterized by a more ambiguous theoretical recognition of the field of the 'social', by a widespread hesitancy about theoretically defending not only distinctive methods of social analysis but also the validity of the social knowledge that they produce, and by a correspondingly greater difficulty in identifying a distinct field of social theory. Thus, relationships between legal scholarship and social theory are increasingly replaced by complex connections between legal theory and various theoretical projects associated with a wide range of intellectual traditions that are not unified by any shared conception of the nature or scope of the 'social' as a research focus.

These developments can be considered in terms of their impact on legal analysis. Of all forms of social theory, Marxist theory probably has had the most direct influence on the study of modern law. Its appeal has depended on its claim to provide a materialist explanation of legal developments; an explanation that showed them as the predictable outcome of a theoretically explicable historical process. Radical legal scholarship in various Western countries, especially from the 1970s, used Marxist theory to develop the idea of law as a site of political struggle, and especially of ideological struggle, following the insights of the Marxist philosophers Antonio Gramsci and Louis Althusser.

The idea of law as a site of ideological conflict, and more generally an emphasis on law's rhetorical significance and its power to shape consciousness, has been retained and developed in current radical or critical legal theory. But, reflecting recent tendencies in social theory, critical approaches in contemporary legal scholarship - in no way limited to those associated with the international Critical Legal Studies movement - now typically resist any idea of objective laws of history or general long-run mechanisms of social change. While ideology remains an important concept, ideology is not to be considered as a distinct object of social analysis but rather as an aspect of intersubjective practices. The idea of society - or any other large-scale social phenomenon - as an object of inquiry has been widely discarded in favour of the study of specific social and political practices and the rhetorics (in which legal ideas often play a prominent part) that accompany them.

Many related tendencies in contemporary social theory are encapsulated in these kinds of scepticism. A distrust of what J.-F. Lyotard (1979) has called 'grand narratives' - theories or perspectives purporting to encapsulate in general terms large swathes of human experience - is founded on a recognition that the ultimate validity of these narratives is necessarily untestable, as well as on a widespread conviction that knowledges adequate to confront the complexities and variety of social experience will necessarily be local rather than general. More specifically, the idea of 'science' as a mark of appropriate social analysis has lost much of its resonance and become associated - perhaps unjustly - with positivist social science and with a lack of sensitivity to the unquantifiable, subjective, transient, immanent but powerful cultural ambiences of social life. It has been associated with the contested claim that clear lines can be drawn between valid and invalid social knowledges, or between truth and falsity in interpretation of social life and social phenomena. Naturalistic models of science have been displaced in favour of models of practice - hermeneutics, literary interpretation, arts of rhetoric, aesthetics, semiotics and linguistic analysis - that offer the prospect of escape from social-scientific protocols of testability and relevance, and promise access to ineffable knowledges that capture the intricacy and indeterminacy of contemporary social experience.

In legal analysis, the issue of the nature of interpretation of legal doctrine remains central and it does so in conditions in which legal regulation proliferates inexorably, assuming a very wide variety of forms. As legal scholarship has accommodated itself to the increasing difficulty of portraying law as an integrated doctrinal system, its concern has focused more sharply on problems of understanding practices of interpretation of doctrine

in these conditions. Classic social theory offered, in the main, accounts of the social origins and consequences of particular historical interpretations of legal materials. But it is often charged with failing to explore legal interpretive or discursive processes themselves. Hence literary theory and other bodies of ideas concerned with the nature of interpretation and its contexts have tended to usurp space previously occupied by social theory as a resource for supplementing and illuminating legal inquiry.

5 Images of contemporary law

The most important forms of late twentieth-century social theory that have been imported into legal scholarship have achieved influence mainly because they relate directly to contemporary problems of legal analysis in grappling with law's perceived unprincipled doctrinal complexity and bulk. Michel Foucault's writings describe the development of particular sociological and psychological discourses that have brought new forms of scientific rationality into governmental regulatory practices (see Foucault, M.). Foucault sees this development as part of the very process that, by merging disciplinary power with claims to expert knowledge, has created the immense diversity of contemporary regulation and made the idea of legal sovereignty sociologically problematic. Law, which Foucault treats as the coercive instrument of sovereign authority, has found its prerogatives of social control engulfed and usurped by numerous new regulatory forms and mechanisms that gain their authority specifically from technical knowledge and practice, developed especially in the social and human (for example, psychiatric) sciences.

Other writers emphasize contemporary law's embodiment in systems that not only float free of the moral groundings that Durkheim sought for legal regulation, but also confound 'modern' views of law as a steering mechanism of social life. Thus, Niklas Luhmann (1989) insists that the complex differentiation of society into a range of distinct, self-sustaining systems of communication condemns law to inhabit only its own discursive system, rather than to have the ability to steer all of society's systems - economic, scientific, cultural, political, for example - in the way that modernity's aspirations for rational government proposed.

Contemporary social theory's image of law and society tends to be one of fragmentation and diversity and of the ungroundedness of social knowledge; an image of specific social spheres governed by values and understandings that have no foundations except in the experience and perspectives of the local milieux in which they arise. The old, 'modern' project of a science of society is seen as embodying untenable assumptions about the generalizability of social experience, and about the possibility of agreement on truth claims underpinning universal systematic knowledge of the nature of society. Thus, the tenets of modernity have increasingly been replaced by postmodern conceptions of law and society (see Postmodernism).

It would, however, be wrong to see the Enlightenment project of social theory as dead. Jürgen Habermas' highly influential work has, in large part, been concerned to find the basis of an underlying rational and moral foundation of social life - in his terms, a communicative rationality - despite the recognition that, in many vital respects, the fragmentation of social life in contemporary Western societies into disparate systems has destroyed possibilities for this kind of moral and rational grounding (see Habermas, J. §4; Communicative rationality; Legal reasoning and interpretation §4). Habermas' analysis of law treats it as precariously balanced between its technical role in mediating economic, political and other systems within society and its moral potential as a set of institutions expressing the values and understandings that arise in the lived experience and interactions of individuals.

Whether or not Habermas' approach is the most appropriate means of pursuing the search for general theory postulating an underlying rationality of legal and social experience, there are good grounds for claiming that this search is unlikely to cease with a postmodern recognition of its complexity and contradictions. Nor is the invocation of science in the interpretation of social phenomena necessarily rendered inappropriate by critiques of positivist science, 'scientific' interpretations of history, or other kinds of 'grand narratives'. The search for a science of society applicable to legal analysis is best understood as an ongoing commitment to make explicit the partial character of all existing understandings of social (including legal) phenomena and to subject these understandings to unending systematic questioning in the light of broadening social observation and ongoing historical experience. Viewed in this way legal and social theory remain interdependent and the project of social theory appears no less vital, if very much more complex and ambiguous and less coloured by optimism, than in the heyday of the classic social theorists.

Socialism

While socialist ideas may retrospectively be identified in many earlier forms of protest and rebellion against economic injustice and political oppression, socialism both as a relatively coherent theoretical doctrine and as an organized political movement had its origins in early nineteenth-century Europe, especially in Britain, France and Germany. It was, above all, a critical response to early industrial capitalism, to an unregulated market economy in which the means of production were privately owned and propertyless workers were forced to sell their labour power to capitalists for often meagre wages. The evils of this system seemed manifest to its socialist critics. Not only was the relationship between workers and capitalists inherently exploitative, and the commodification of labour an affront to human dignity, but it generated widespread poverty and recurrent unemployment, massive and unjust inequalities of wealth and economic power, degrading and soul-destroying work, and an increasingly atomized and individualistic society.

Socialists were not alone in criticizing some of these features of industrial capitalism and its accompanying ideology of economic liberalism. In particular, antipathy towards individualism was also a characteristic of conservative thought. But whereas conservatives found their inspiration in the hierarchically structured organic communities of the past, and were deeply hostile to the political radicalism of the French Revolution, socialists looked forward to new forms of community consistent with the ideals of liberty, equality and fraternity. For them, the evils of capitalism could be overcome only by replacing private with public or common ownership of the means of production, abolishing wage labour and creating a classless society where production geared to capitalist profits gave way to socially organized production for the satisfaction of human needs. In such a society, the human potential for a genuinely 'social' mode of existence would be realized, with mutual concern for others' wellbeing rather than unbridled pursuit of self-interest, with cooperation for common ends rather than competition for individual ones, and with generosity and sharing rather than greed and acquisitiveness - a truly human community.

For most nineteenth-century socialist theorists, the historic task of creating such a society was assigned to the organized industrial working class; most notably by Marx, the pre-eminent figure in the history of socialism. It was Marx who (along with Engels) provided the socialist movement not only with a theoretically sophisticated economic analysis of capitalism and a biting critique of its social consequences, but also, through his scientific, materialist theory of historical development, with the confident belief that the inherent contradictions and class antagonisms of capitalism would eventually give birth to a socialist society.

In marked contrast to such earlier optimism, contemporary socialists are faced with the continued resilience of capitalist societies and the collapse of at least nominally socialist regimes in the USSR and elsewhere, regimes in which state ownership and centralized planning have been accompanied by political repression and economic failure. For those who reject the idea that a suitably regulated form of welfare capitalism is the most that can be hoped for, the task is to construct some alternative model of a socialist economy which is preferable to this yet avoids the evils of centralized state socialism.

1 Defining socialism

The term 'socialism' was first used by Owenites in Britain and by Saint-Simonians in France in the 1820s and 1830s, and soon became widely adopted to refer both to a body of ideas critical of capitalism and to the future society that would or should replace it. But disputes about the meaning of 'socialism' - itself sometimes contrasted with 'communism', at other times taken to include it as a subcategory (see Communism) - have been endemic to its history, even more so than with its two main ideological counterparts, liberalism and conservatism. An enormous variety of theoretical positions and political movements have been termed 'socialist', by proponents and critics alike. Particular versions may be indicated by some qualifying term - as in state socialism, market socialism, guild socialism, revolutionary socialism, scientific socialism, ethical socialism, even national socialism (fascism); but there is no agreed classification of types since the relevant basis for this is itself subject to dispute. For some, what is crucial is the political means through which the desired future is to be achieved - for example, revolution or reform; for others, the specific nature of socialist economic institutions - for example, state planning or decentralized producer democracy; and so on.

An especially significant issue is whether socialism is to be defined normatively or institutionally: in terms of a set of values or ideals which socialists aim to realize, and which provide the basis for their critique of capitalism; or of the specific character of the economic institutions of a socialist society. The latter option has the obvious disadvantage of leaving unmentioned just why this institutional form should be seen as preferable to capitalism, and what makes it a system worth fighting for. The former option, by leaving the institutional requirements for socialism entirely unspecified, makes it a purely empirical question whether, as many who are now termed 'social democrats' would claim, capitalism can be modified so as to realize socialist values: there would then be no logical contradiction in calling such a capitalist society 'socialist'. But given the socialist tradition's opposition to capitalism on the grounds that no such modification is possible, it seems preferable to regard this social democratic thesis, if true, as a refutation of socialism, rather than as consistent with it (see Social democracy).

So it seems best to include in the definition of socialism both normative and institutional elements. For the socialist, the economic institutions of capitalism embody certain features and/or generate certain consequences that are objectionable from the standpoint of certain values; and there are possible alternative forms of economic organization which would either fully realize those values, or at least be markedly preferable to capitalism when judged in these terms. This, of course, is little more than a definitional schema, and leaves room for many varieties of socialism with respect both to the specific values involved and the specific form which a socialist economy might take.

On the latter question, while socialists have typically argued for the replacement of private by social, public or common ownership of the means of production, they have differed about what exactly this should involve - ownership by the state, by functional associations or local communities, by the members of producer cooperatives, and so on - and indeed about whether it is ownership or control that is crucial. Likewise, different solutions to the problems of economic coordination and allocation have been proposed: centralized planning by the state, decentralized planning, or even a market system shorn of its distinctively capitalist property relations. These different proposals are themselves often related to different views as to precisely what it is about capitalism that is objectionable and/or causally responsible for its ills: whether all relations of market exchange are undesirable, or only those involving the sale and purchase of labour power; whether it is private ownership of the means of production that is chiefly responsible for unjust inequalities in the distribution of economic goods, or the operation of a competitive market; and so on.

On the former question, of the specific character of socialist values, perhaps the main source of variation is the attitude taken towards political liberalism (see Liberalism). Some socialists have seen their task as engaging in an immanent critique of liberal democracy, broadly endorsing its declared values of freedom and equality but trying to show that their distinctively liberal interpretation is unduly narrow and restrictive: for example, by arguing for the extension of individual rights to include social and economic ones, and of democracy to include control over economic decisions. From this standpoint, liberal democracy is to be transcended - in the Hegelian sense of 'going beyond yet preserving' - rather than totally rejected; and the ideal of community is understood to involve harmonious relations between individuals who respect and enjoy one another's freedom. For others, by contrast, political liberalism - including its emphasis on the rule of law - is no more than an ideological facade of capitalism, so that, for example, its conception of legally enforceable individual rights has no place in a socialist society; and the value of community is understood in a more holistic manner.

With these broad points about the definition and variations of socialism in mind, we can proceed to examine some of the main arguments for socialism and the critical responses to these, focusing in turn on debates about economic efficiency, human wellbeing, democracy and power, and distributive justice. While the case for socialism typically begins by attributing various ills to capitalism, it depends also on being able to show that there is some alternative system in which these would be absent or greatly reduced. Correspondingly, critics of socialism may deny either that the supposed ills are properly regarded as such, or that they are attributable to capitalism intrinsically rather than to contingent features of particular capitalist societies; and/or they may argue that the proposed socialist alternative fails to overcome these ills, or that it does so only at the cost of producing further ones of its own.

2 Efficiency, planning and markets

Socialist critics of capitalism have frequently pointed to its economic failings. Its reliance on anarchic market forces makes it liable to cycles of booms and slumps, subjects workers to recurrent periods of unemployment and

permanent insecurity, and fails systematically to make effective use of human and natural resources. For all its dynamism in producing goods to satisfy increasingly exotic consumer preferences, it leaves many basic needs unmet. It underprovides public goods, cannot incorporate the social costs of economic activity and is destructive of environmental and other preconditions of long term economic development. For many socialists the solution has been seen to lie in a centrally planned economy in which resources can be effectively and rationally directed to satisfy human needs while also meeting other social and ethical objectives.

This case against the market and in support of planning has been met by three main kinds of argument: neoclassical, motivational and epistemic. Neoclassical economic theorists claim that a market economy is demonstrably ‘efficient’ in the sense of being Pareto-optimal: the outcomes it produces cannot be departed from without at least some individual(s) experiencing a reduced level of preference satisfaction (see Economics and ethics §3). Admittedly this can be shown only for ‘ideal’ markets: for example, where there are no public goods or externalities. But such cases of (actual) ‘market failure’, it is claimed, can be dealt with either by limited forms of state intervention, or by assigning property rights to currently unowned goods and resources.

The motivational argument is that socialism must fail because it makes unrealistic demands on the potential altruism of economic agents. Workers must be expected to perform their tasks without the promise of differential material rewards, and planners to put aside their own interests in making economic decisions. But humans are by nature primarily self-interested beings: the supply of altruism is strictly limited and cannot be relied upon as the basis for economic organization. The market takes advantage of this fact by providing incentives for workers and managers that ensure the allocation of resources to those spheres of production where they will be most beneficially employed. Without such incentives, socialist alternatives to the market will inevitably fail.

The epistemic argument, developed in the Austrian school of economics and especially by Hayek, is that only the market can solve the economic problem of ignorance (see Hayek, F.A. von §2). This problem is due to the division of knowledge in society - its dispersal among different economic agents; and to the practical nature of much of this knowledge (knowledge ‘how’ rather than knowledge ‘that’), which cannot be articulated in propositional form, and hence cannot in principle be acquired by a centralized planning agency. Thus no economic plan can gain access to and utilize all the knowledge relevant to economic decisions. By contrast, the price mechanism manages to distribute the knowledge relevant for economic coordination while allowing individual agents to rely on their own ‘local’ knowledge in the decisions that concern them.

Two main responses to these arguments may be made by socialists. The first is broadly to accept them, but to argue that they do not amount to a defence of capitalism but only of the market, which may itself take either capitalist or non-capitalist forms. This is the line taken by market socialists. The market is, *ceteris paribus*, the most efficient and dynamic economic mechanism, but it can be constructed in a form compatible with socialism by eliminating its distinctively capitalist features, notably private ownership in the means of production and wage labour. Among numerous versions of market socialism, probably the closest to traditional socialist aspirations involves social ownership in the form of workers’ cooperatives whose assets are either directly owned by their members or leased to them by the state.

The second response is to challenge those arguments for the economic superiority of the market. For example, the neoclassical concept of efficiency may be criticized for defining this in relation to the satisfaction of individual wants or preferences, whatever their specific content or rationale. To show that markets are efficient in this sense is to show very little: it ignores the distinction between wants and needs, and fails to discriminate between preferences in terms of their contribution to human flourishing or wellbeing.

To the motivational argument that socialism makes unrealistic demands on altruism, there are several possible replies. One is to say that egoism is not a part of human nature, but the product of living in a capitalist society: a far greater degree of altruism can be expected in the different institutional context of socialism, either because such altruism is itself natural to humans, but inhibited by capitalism, or because human motivations are highly malleable in this respect. Alternatively, the ways in which self-interest and altruism are typically conceived and contrasted in these debates may be challenged. Actions oriented towards the wellbeing of others, and the relationships within which these take place, are often themselves a significant source of wellbeing to those concerned (see Human nature §3). The kinds of self-interest the market relies upon are unduly narrow and restrictive in character: socialism does not require self-sacrificial forms of altruism, but instead makes possible the satisfaction of a more

extensive and fulfilling range of interests. But the problem remains of how workers in a non-market economy are to be motivated to move to where they are most needed.

Against the epistemic argument for the market it may be objected that the market's informational virtues are much exaggerated. The price mechanism by no means distributes all the information relevant for economic coordination: indeed competitive pressures often generate disincentives to communicate relevant information about other producers' plans, scientific and technical innovations, and so on. Nor is the information required for coordination the only information relevant for economic activity, as the frequent exclusion of environmental impacts from market decisions illustrates. Admittedly, even if such criticisms of the informational virtues of the market can be sustained, there remains a strong epistemic case against centralized economic planning. Yet there may be institutional forms superior both to markets and to centralized planning for at least some tasks, such as those involved in the organization of scientific communities. Whether these provide plausible models for economic coordination is unclear.

3 Wellbeing and the human good

The replies to both the neoclassical and motivational arguments for the market involve claims about the nature of the human agent and of human wellbeing. In doing so they express a recurrent concern on the part of its socialist critics with the market's failure to establish the necessary conditions for human flourishing, and its encouragement of attitudes, motivations and character traits damaging both to those who acquire these and to those affected by them. For example, it is claimed that the market issues in such vices as competitiveness, avarice, egoism, possessiveness and vanity, all at the expense of the proper virtues of character and the humanly beneficial social relationships of community; that the pleasures of private consumption are mistakenly privileged over the more fulfilling demands of public life; and that capitalist forms of production deny to workers the exercise both of their active and creative capacities in work and of their deliberative capacities in the democratic control of the productive process (see Work, philosophy of §2).

Marx's critique of capitalism as a condition of 'alienation' is typical here (see Alienation), but similar arguments against capitalism for its development of particular kinds of human character and social relationships incompatible with human wellbeing are to be found amongst other socialist theorists, from Morris and Tawney in the British tradition to Fromm and Marcuse in the continental. In current philosophical terminology such criticism is 'perfectionist' in form: it claims that social and political institutions should be judged by reference to a specific conception of the human good (see Perfectionism). It is often broadly Aristotelian in content, seeing human wellbeing as consisting of the development and exercise of species powers and capacities. Hence it rejects, *inter alia*, the utilitarian, preference-based accounts of wellbeing that often underpin the neoclassical concept of efficiency: economic institutions are to be assessed not by their ability to satisfy given preferences, but in terms of the nature and value of the preferences they themselves encourage and make it possible to satisfy (see Welfare §1).

Two kinds of response may be made to such claims. The first, which is typical of much modern liberal thought, is to reject perfectionist arguments altogether. It is a mark of liberal institutions that they be neutral between different conceptions of the good (see Neutrality, political). Such neutrality is especially desirable given the pluralistic character of modern societies, in which diverse and irreconcilable conceptions of the good are espoused. In this situation, perfectionism must imply the imposition of a contested conception of the good by coercive means, and hence a political practice which is paternalistic or even authoritarian. By contrast, the market is consistent with liberal neutrality. It provides an economic framework in which individuals with quite different ends and beliefs about the good can pursue these through mutually beneficial free exchanges.

The second response accepts the legitimacy of perfectionist arguments but denies that markets are incompatible with the human good. This may be argued either by denying that the market necessarily has the ill effects that socialists attribute to it, or by attributing to the market effects deemed highly desirable in terms of some alternative conception of the good. In the latter case it may be claimed, for example, that the market has the great merit of fostering individual autonomy; although socialists may respond to this by arguing that the development of such autonomy in fact requires the existence of certain kinds of social relationships which the market tends to undermine.

4 Democracy, power and freedom

The claim that socialism produces the conditions for the realization of liberal political values has been central to arguments for socialism that appeal to the values of democracy and freedom. The argument can take both weaker and stronger forms. The former asserts that many of the standard liberal rights and freedoms are empty without the material conditions for their effective exercise, which the market systematically fails to guarantee. This view is sometimes stated in terms of a criticism of ‘negative’ conceptions of liberty as the absence of coercion, proposing instead that these material conditions should be included in the definition of liberty itself (see Freedom and liberty §3). Alternatively it may simply be argued that if (negative) liberty is valuable, then so too are the conditions for its exercise. In response to the objection that the market’s unequal distribution of material conditions is the unintended consequence of a spontaneous order, and hence should not be seen as a constraint on freedom, the socialist may argue that the market is not the outcome of natural events but of social decisions aimed at its creation and/or maintenance, that its distributive consequences are both foreseeable and alterable, and that there is no justification for restricting one’s conception of liberty to the absence of intentional constraints.

The stronger form of the claim that socialism realizes liberal values is that it represents their consistent application to the economic sphere. A version of this position can be found in Marx’s early writings, in which the ‘ideal’ community of the liberal democratic polity is contrasted with the egoistic realm of modern civil society; correspondingly, the rights of citizens exercised through their participation in the political community are set against the ‘rights of man’ exercised by the private individuals of civil society. The project of socialism is then expressed as bringing the ideal world of the polity down to reality through the democratic transformation of economic life. This strategy of pointing to the divergence between the rights and freedoms of the ideal liberal political order and their absence in the economic sphere has also been employed in other contexts: for instance, by contrasting democratic participation in the political system with the authoritarian nature of power relationships within the capitalist firm.

To such claims that socialism represents the completion of the democratic project, two main responses may be made: the liberal and the radical. The first denies that there is a conflict between the capitalist economic order and the liberal polity: rather, the existence of a market order, in which individuals enter freely into voluntary contractual relations, is itself a condition of the political rights and freedoms that define the liberal polity. It is not a sufficient condition: authoritarian states are compatible with capitalism. However, it is a necessary condition: political liberties are only to be found in free market economies. The socialist order, by concentrating economic, social and political power, destroys the space of civil society in which individuals enter into voluntary relations independent of the state, and which provides the cultural and social conditions for opposition to state power (see Civil society). This objection applies primarily to centrally planned socialist economies with state ownership of the means of production, and is often endorsed by market socialists as a further reason to support their own proposals. Alternatively, it may be argued that the existence of such concentrations of economic and political power is compatible with restraint in its exercise, and that the absence of liberal political rights in state socialist societies such as the erstwhile USSR can be explained by reference to factors other than the absence of markets - for example, to the lack of liberal democratic institutions prior to their revolutionary transformation.

The second, radical response is concerned not so much with the cogency of the socialist critique of liberalism but with its completeness. In effect it extends the socialist criticism of liberalism to socialism itself. By placing its emphasis on the economic sphere, socialism has been blind to other sources of power, in particular those concerned with race and gender. Thus the feminist criticism of traditional socialism: that by confining its attention to the ‘public’ sphere of economic and political life it fails, like liberalism, to address the primary origin and location of women’s oppression, in the ‘private’ sphere of the family and in ‘personal’, including sexual, relations between men and women (see Feminist political philosophy §4). Two replies may be made by socialists to this kind of critique. The first is to claim that these other asymmetries of power can themselves be explained in terms of the organization of economic production. The second is to accept the existence of diverse sources of social power and to re-conceptualize the traditional socialist project in the economic sphere as simply one component of a wider programme of human emancipation.

5 Distributive justice

The final set of arguments for socialism to be considered here are distributive ones. Capitalism is criticized for the unequal and/or unjust distribution of material, social and cultural goods. But this criticism takes a number of

different forms. For some socialists, the preferred distributive principle is strict equality, either contrasted with justice or regarded as its proper interpretation. Others espouse some not necessarily egalitarian principle of justice: distribution according to need is the most common, as in the well-known principle, ‘from each according to their ability, to each according to their needs’; but appeal may also or instead be made to a principle of desert, such as reward in proportion to contribution. While the last of these is rarely proposed as the sole distributive principle for a socialist society, it has often figured in socialist criticisms of capitalism, especially in the claim that capitalist profits are undeserved and hence unjust. But there is disagreement among socialists about whether the distribution of goods in a non-capitalist market economy would be unjust from this standpoint.

Defenders of capitalism have sometimes argued that it can be shown to be just by reference to a principle of desert: for example, by arguing that profits are a deserved reward for risk-taking. But more commonly they reject altogether the legitimacy of desert-based, need-based, egalitarian or any other so-called ‘patterned’ principles of justice in judging economic systems, on the grounds *inter alia* that any attempt to realize such patterns will involve unjustifiable and systematic coercion by the state. Instead, it is argued, justice should be understood as a purely ‘procedural’ concept: distributions are just if they are the outcome of fair or appropriate procedures, whatever the resulting pattern may be. An especially favoured procedure is voluntary exchange between free and equal parties. It is then claimed that since capitalist market transactions consist exclusively of such exchanges, capitalism is a just system (see Libertarianism; Nozick, R. §2).

For socialists, such procedural definitions illicitly reduce the concept of justice to that of (negative) liberty. But it may also be argued that even if adopted, they would fail to show that the outcomes of the transactions between capitalists and workers are just. For although the sale of labour power in return for wages is a transaction between formally or legally free and equal parties, there is an absence of substantive freedom on the part of workers, coupled with marked asymmetries of power. In addition, socialists may point to the historical origin of most current capitalist holdings of private property in past acts of theft, fraud, violence or state coercion.

While arguments for socialism couched in terms of distributive justice and equality have been widely employed, they have often been criticized by Marxists, partly for assuming that the crucial defect of capitalism lies in the improper distribution of goods in the sphere of exchange, rather than in the power relations in the sphere of production consequent upon capitalist property relations. Hence emphasis is placed instead on the concept of exploitation, understood as the extraction by capitalists of surplus value from workers which accrues to the capitalist in the form of profits - something that cannot be remedied by higher wages but only by the abolition of wage labour. Whether this concept of exploitation and its associated theory of value can be sustained is much disputed amongst socialist theorists, some of whom have argued instead for a purely distributional interpretation of the concept: for example, that someone is exploited if they would be better off than they now are had there been an initially egalitarian distribution of ownership rights over the means of production.

6 The future of socialism

The near universal collapse of nominally socialist regimes since the late 1980s has led many critics of socialism to proclaim its death. But these regimes have always had their socialist critics also, for many of whom these historic events may prove welcome, not least in undermining the previously hegemonic status of Marxist-Leninism in socialist theory and practice, and the marginalization of other significant traditions of socialist thought. Thus one response to the political and economic failures of state socialism has been to return to some of these earlier, non-centralist socialist traditions, and attempt to re-work them for contemporary purposes. One such attempt is that of the ‘associational socialists’ who, taking their inspiration from nineteenth- and early twentieth-century guild socialism and syndicalism, propose independent and self-governing functional associations as the units of political and economic authority, rejecting both state and market.

By contrast, as noted earlier, the project of ‘market socialism’ is to construct a non-capitalist market system operating within liberal democratic political institutions. This position has the virtue of being able to provide a relatively well-articulated alternative to capitalism which takes account of the powerful objections to centralized planning. Yet its acceptance of market forces, of individual self-interest and relationships of exchange and competition, makes it appear to non-market socialists a poor substitute for the ‘truly human’ community to which they aspire. To this its proponents may reply that one should not aim at a single, monolithic ideal of community for society as a whole, but accept instead a more differentiated conception of social existence in which different forms

of human wellbeing are realized within different spheres or domains, of which the economic is but one. Yet it remains unclear whether market economies are compatible with, or inimical to, the flourishing of significant forms of community outside the economic sphere (see Communty and communitarianism).

Further, like any market system, market socialism is subject to a range of objections from an ecological or environmental perspective. The market fails to take account of the environmentally destructive consequences of economic growth; it is unable to incorporate the interests of those who cannot engage in market transactions - whether the poor, members of future generations, or non human beings; and it encourages people to misidentify the primary source of wellbeing as the endless pursuit of consumer satisfactions. Indeed, whilst the environmental movement has presented a serious challenge to the tendency of much socialist thought to conceive of human emancipation as requiring the subordination of nature to human ends, it has also given new life to many traditional socialist objections to the market: its remarkable ability to generate collectively irrational outcomes from individually rational behaviour, including the underproduction of public goods and the overproduction of public ills. For both political ecologists and socialists, there is a vast range of social problems which require collective rather than individual action for their solution, and a continuing need for forms of ethical and political commitment that the market both fails to recognize and may often undermine (see Green political philosophy).

Society, concept of

The term 'society' is broader than 'human society'. Many other species are described as possessing a social way of life. Yet mere gregariousness, of the kind found in a herd of cattle or a shoal of fish, is not enough to constitute a society. For the biologist, the marks of the social are cooperation (extending beyond cooperation between parents in raising young) and some form of order or division of labour. In assessing the merits of attempts to provide a more precise definition of society, we can ask whether the definition succeeds in capturing our intuitive understanding of the term, and also whether it succeeds in identifying those features of society which are most fundamental from an explanatory point of view - whether it captures the Lockean 'real essence' of society.

One influential approach seeks to capture the idea of society by characterizing social action, or interaction, in terms of the particular kinds of awareness it involves. Another approach focuses on social order, seeing it as a form of order that arises spontaneously when rational and mutually aware individuals succeed in solving coordination problems. Yet another approach focuses on the role played by communication in achieving collective agreement on the way the world is to be classified and understood, as a precondition of coordination and cooperation.

1 Defining social interaction

Max Weber defines social action as 'action in which the meaning intended by the agent or agents involves a relation to another person's behaviour' (1978: 7), and a social relationship exists 'when several people reciprocally adjust their behaviour to each other with respect to the meaning they give to it' (1978: 30) (see Social action). Thus several people acting in a similar way need not be engaging in social action, but two cyclists who try to give way to each other are. Weber excludes non-human animals from the realm of the social on the grounds that they are not capable of the intentions that might give meaning to their behaviour. (His paradigm of 'meaningful action' is the rational pursuit of a consciously chosen goal.) In that respect, Weber's definition of the social may seem unduly narrow, but it also seems to be over-inclusive. A population of individuals who took account of each other's behaviour only to the extent of seeking to avoid collisions would not on that account qualify as living a social way of life, not at least by any intuitive criterion. We may also find it odd that cooperation is not a necessary feature of society on Weber's account.

Alfred Schütz (1932) seeks to improve on Weber's definitions, telling us that we have a social relationship where there is mutual awareness of the way each sees the other (see Schütz, A.). This requirement identifies an important feature of human interaction, but it is still not clear that it captures what makes it 'social' interaction. A sophisticated form of the predator-prey relationship, in which the predator is aware that the prey is aware of it and vice versa, would seem to qualify as a social relationship by this criterion. More promising is Schütz's definition of 'social interaction', which involves, in addition to the requirement of mutual awareness, an attempt by one party to affect the consciousness of the other. Thus social interaction is defined as an attempt to affect another's state of mind in which the other is aware of one's intentions and is also aware that one knows that they are aware of one's intentions. Schütz also notes that this is what we call communication. The work of H.P. Grice develops this approach to communication, invoking yet more complex levels of mutual awareness. Though Grice himself is not concerned to define the social, the kind of mutual awareness to which he appeals is clearly not confined to linguistic interaction, and the idea that communication is a central feature of social interaction has proved fruitful (see §3 below).

2 Game theory and social order

The effect of an exclusive focus on social interaction as a relationship between individuals is to make social order seem a merely incidental and inessential feature of social life. Intuitively that is odd. More recent individualist approaches employing the resources of game theory (see Rational choice theory §2) have taken it for granted that both social order and cooperation are defining features of social life, and have seen it as their task to demonstrate that these features can be understood as the outcome of interactions between individuals pursuing their own individual purposes.

In some respects, game theory represents a further refinement and idealization of the assumption of mutual

awareness. Individuals are assumed to be instrumentally rational in that they are seeking to maximize the satisfaction of their preferences. This need not mean that they are selfish, but it does mean that the goals they are pursuing are their own and not, for example, a collective goal. It is also ‘common knowledge’ between them that they are rational. (This amounts to saying that each knows that the others know this, and knows that the others know that they know this, and so on *ad infinitum*.) It is also assumed that there is common knowledge of the possible choices of action open to each party and of the payoffs attached to possible outcomes. There is to be no communication between individuals, but each is able to assess what it would be rational for others to do and can take that into account in deciding what it is rational for them to do. The claim is that, given these assumptions, where there is a mutual interest in coordination (for example, in everyone driving on the same side of the road), individual rational choices will give rise to uniformities in behaviour without the need for explicit agreement or social sanctions. Lewis (1969) makes this thought the basis of his definition of ‘convention’ as - very crudely - a regularity in behaviour that everyone keeps to because it is in their interest to do so given that everyone else does (see Social norms §1). Using this account of convention, Lewis seeks to account for linguistic and other forms of communication as forms of game-theoretically rational action with the complexity of levels of mutual awareness to which Grice appeals.

The game-theoretic approach promises not just an explanation of social order but an account of what social order is, for clearly not just any regularity in the behaviour of a population will count as an example of social order. Social order arises, on this view, when rational and sufficiently mutually aware individuals succeed in solving coordination problems. However, it is controversial whether the rational agents of game theory can ever do this, and it is in any case widely conceded that there are aspects of social order that cannot be understood in this way. There are many circumstances in which, though the collective interest would be served by everyone obeying a rule, it is in the individual’s interest to break it. In these circumstances game theory predicts that no one will obey the rule and so all will lose out. This is known as the ‘free-rider’ problem. It does not help to appeal to sanctions against rule breakers, for we then need to explain how it could be rational for one individual to seek to impose sanctions on another, and the free-rider problem arises all over again. Thus the game-theoretic approach fails to explain a form of cooperation that is central to human social life.

One way of responding to this failure is to modify our assumptions about individual motivation, for example by building in a degree of concern for the interests of others, though interestingly it is not clear that this is enough. Elster (1989) argues that we also need to invoke a respect for social norms, but this suggestion faces a dilemma. Either we appeal to a respect for norms in general along the lines of Kant’s categorical imperative (see Kant, I. §11), whose implications threaten to be insufficiently determinate to help with our problem, or else we appeal to the respect individuals feel for the norms of their particular society, in which case we beg the question of the explanation of social order by treating social norms as already given.

3 Society as a system of communication

For G.H. Mead and for the Durkheimian tradition, especially as it has been developed in anthropology, the key feature of social interaction is communication (see Mead, G.H.; Durkheim, É.). Not just language but action in general is seen as having communicational or expressive significance, and its function is not simply to transmit useful information but to get agreement on the way the social world is to be classified and understood. A shared way of interpreting and defining reality, sustained by its expression in language, ceremony and ritual, is on this view a precondition, not only of mutual intelligibility, but of the kind of coordination and cooperation between individuals that game theory has such difficulty in explaining. Communication is also an important feature of animal social life, and it is possible to see it as having a similar function there too, even if the forms of expression and the schemes of classification involved are much more restricted.

Even so, it is clear that not just any system of communication constitutes society. The simple transmission of information, as in alarm calls in flocks of birds, is not enough. Nor is it enough that communication yields a shared scheme of classification or definition of reality. The defence of territorial boundaries, for example, yields an agreed definition of reality that is consistent with relationships between individuals being wholly antagonistic. It seems best to say that we have something we can call society only when the agreed definition of reality provides for the possibility of cooperation; though if we are to avoid seeing cooperation between parents in raising offspring as in itself amounting to a social way of life, we must add that the agreement on ways of defining reality must

extend beyond two individuals. This is not an arbitrary restriction, for beyond that number agreement becomes significantly more difficult to achieve. Inevitably, questions of classification will sometimes be a matter for dispute, making claim and counterclaim endemic to social life. Thus while cooperation is, by this definition, a necessary feature of social life, so too is a distinctively social form of conflict.

For the Durkheimian tradition, the key distinguishing feature of *human* society is the normative dimension, the existence of shared standards of correct thought and behaviour. This means not simply the fact of general conformity to standards of correct thought and behaviour but the fact of those standards being collectively policed. For Durkheim, the authority behind social norms is the authority of the collective viewed as an organized group, but Mead's idea of 'the generalized other' suggests a different view. In the absence of shared standards of correctness and legitimacy, agreement emerges, if it emerges at all, from the play of power in disputes between interested parties, supported perhaps by friends and allies. The existence of shared standards means that parties in dispute can appeal to the disinterested jury of others in general, and that they will tend to accept the verdict of that jury. Some standards, of course, are likely to be policed in a more organized way (for example the criminal law), but more generally, and more fundamentally, shared standards are policed by the authority of others in general. For Mead, it is by taking up the point of view of others in general that an individual comes to possess their own sense of what is correct and legitimate, and also a sense of themselves as an individual.

If communication is to be seen as the basis of society, it cannot be viewed as a form of instrumentally rational action of the sort modelled by game theory (see §2 above). Communication must be capable of operating independently of, and at a more primitive level than, the degree of rationality and mutual awareness assumed by game theory. As social beings, we must be supposed to possess an urge to express our own view of things, and also a tendency to be influenced by the way others see things, that is prior to our rationality and which constitutes a distinctive source of motivation in its own right. Thus Jürgen Habermas (§2) distinguishes between instrumental action which is 'oriented to success', and communicative action which is 'oriented to reaching understanding'. Habermas also stresses that, in a context of shared standards of correctness, acts of communication take on the force of legitimacy claims. The anthropologist Mary Douglas (1977) makes a similar distinction between instrumental action and expressive action, but emphasizes the competitive aspect of social communication. Our expressive activity reflects a need to give meaning to the world, a need, in fact, to construct an intelligible world as a condition of remaining sane. But my attempts to win agreement to my interpretations of reality may conflict with yours. To see society as a system of communication is to see it as a battleground of conflicting interpretations of reality in which the price of failure to win agreement is exclusion from social interaction.

4 Social groups

For methodological individualists like Weber, talk of social collectivities can only be a way of talking about 'actual or possible social actions of individual persons' (see Holism and individualism in history and social science). Elster (1989) offers one way of putting flesh on this idea, defining a society as a geographical area for which there is a local maximum of the number of transactions between the individuals in the area divided by the total number of transactions in which those individuals are involved. Shorn of the reference to a geographical area, this could serve as a definition of social class, for class boundaries are certainly barriers to social interaction, but most social groups are thought of as having a greater degree of unity than this.

For Georg Simmel (1908), the unity of a social group consists in the fact that its members think of it as possessing a unity. Gilbert (1989) develops this idea in a way that recalls Rousseau's distinction between the general will and the will of all (see Rousseau, J.-J. §3). Appealing to what she argues is the central use of the first person plural 'we', she defines a social group as a 'plural subject' constituted by the fact that each of a number of individuals finds it appropriate to use 'we' in attributing purposes, activities, beliefs, and so on, to themselves jointly rather than severally. The idea of a plural subject offers us a less individualist conception of social cooperation than that which emerges from game theory, though seen from a communication system perspective (see §3 above), the idea that 'we' constitute a plural subject is just one of the agreed ways of defining reality which can serve to facilitate coordination and cooperation.

Socinianism

Socinianism was both the name for a sixteenth- and seventeenth-century theological movement which was a forerunner of modern unitarianism, and, much less precisely, a polemic term of abuse suggesting positions in common with that 'heretical' movement. Socinianism was explicitly undogmatic but centred on disbelief in the Trinity, original sin, the satisfaction, and the natural immortality of the soul. Some Socinians were materialists. Socinians focused on moralism and Christ's prophetic role; the elevation of reason in interpreting Scripture against creeds, traditions and church authority; and support for religious toleration. The term was used polemically against many theorists, including Hugo Grotius, William Chillingworth, the Latitudinarians, and John Locke, who emphasized free will, moralism, the role and capacity of reason, and that Christianity included only a very few fundamental doctrines necessary for salvation.

1 The Socinian movement

Socinianism was founded by Laelius and Faustus Socinus, and was the name given to an unorthodox evangelical theological movement which originated in Italy and spread first to Poland, and then to the Netherlands and England. At its height the academy of the Socinian Minor Church in Racov had over a thousand students, and its press published works which were disseminated in many languages and countries. In many countries, however, Socinians were punished or executed as 'heretics' or forced into exile, and the Socinian church was crushed in Poland in 1660. Many Socinians then settled in the Netherlands. The leading Socinian authors in the generations after Faustus Socinus were Johann Crell, Johann Völkel, Johann Von Wolzogen, Andreas Wiszowaty and Samuel Przypkowski.

2 The Trinity and satisfaction

Socinianism was explicitly undogmatic, and many of its beliefs changed over time, but throughout it centred on disbelief in the Athanasian Trinity of three co-eternal consubstantial persons in one Godhead in favour of the belief that Jesus was a divinely inspired man who brought the definitive revelation or Word of God, and that the Holy Spirit was a power or energy of God. Jesus was distinguished from the rest of mankind by his perfect holiness of life, by being conceived by the Holy Spirit and by being endued with divine wisdom. At his resurrection he had been given power to rule over the world. Some Socinians argued that a plurality of infinite persons in one God was impossible. Intimately connected to denial of the Trinity was denial of orthodox Calvinist accounts of Christ's satisfaction. It was held by many Socinians that Christ had not paid an equivalent for humanity's sins in order to satisfy God's justice; his mission was centrally prophetic rather than priestly. God forgave sins, rather than receiving payment for them.

3 Original sin, mortalism and materialism

Socinians denied original sin and held the 'mortalist' belief that human souls were not naturally immortal. For Socinians, Adam's sin had not corrupted the power of his posterity to choose good over evil. They maintained that humans had free will, and opposed predestination, in part to protect God from responsibility for sin. They simultaneously maintained that humans were sinful, by emphasizing both that individuals were responsible for their own sins and that all generations had engaged in extensive sinning. They depicted naturally mortal humans as left to their natural mortality unless saved by the power of the Spirit in following the commandments of Jesus. They denied both the natural immortality of the soul and the resurrection of the earthly body in favour of belief that there would be a selective resurrection of the saved providing them with immortality in celestial bodies. The eternity of punishment for sin was denied in favour of belief in an eternal fire causing annihilation of the damned. Some Socinians combined mortalist belief with materialism and held that matter was coexistent and coeternal with God; Faustus Socinus himself held that the world had been made from pre-existent matter. Many Socinians depicted Christ as bringing information about an afterlife and a promise of immortality inaccessible by reason alone, with Christ's resurrection itself serving as a central testimony to immortality.

4 Reason and toleration

Socinians placed a heavy emphasis on the role of reason or 'right reason' as the sole and final interpreter of

Scripture, and on Scripture as the definitive revelation of God's will. Scripture was said to be perspicuous to reason and Socinians attacked the authority of traditions, church authority and creeds. By the mid-seventeenth century Joachim Stegmann was arguing that nothing in the Bible exceeded human understanding. Many in the later generations of Socinianism suggested that contemporary orthodoxy was overly influenced by the Platonic and Neoplatonic philosophy of the early church, depicting this influence as buttressing belief not just in the Trinity but also in the natural immortality of the soul. Elevating reason against church authority, and personally attacked as 'heretics' for their beliefs, Socinians supported religious toleration and argued that the state was dedicated to purely natural ends. Many were pacifists.

5 'Socinianism' as an accusation and John Locke

The polemic accusation of Socinianism was regularly made in the seventeenth century against many thinkers, including Grotius, Chillingworth and Locke. Grotius' *De Veritate Religionis Christianae* omitted original sin and the atonement, but he published elsewhere in defence of the satisfaction and he believed in the resurrection of the same bodies (see Grotius, H.). William Chillingworth and the Latitudinarians emphasized the limited fundamentals of Christianity, the role of reason, and the centrality of morality in Christianity, but explicitly endorsed the Trinity, the atonement, and the immortality of the soul (see Chillingworth, W.; Latitudinarianism). The most important philosopher accused of Socinianism was John Locke. A series of writers declared his *Reasonableness of Christianity* 'all over Socinianized'. Leibniz described Locke as 'inclined' to Socinianism for his recognition of the possibility that matter might think, because this rendered it impossible, in Leibniz' view, to prove the soul's natural immortality. Bishop Edward Stillingfleet argued that Locke's epistemology 'favoured' Socinianism for his arguments about the limitation of our knowledge about substance, which undercut Trinitarian explications of the consubstantial Godhead.

Locke's library included many Socinian works, some of which he read carefully. His *Reasonableness of Christianity* was close to Socinianism in a number of ways. It interpreted Adam's Fall as not involving a 'corruption of human nature in his posterity'; discussed Christ's mission as essentially prophetic and especially kingly rather than priestly; avoided the satisfaction; emphasized Christ's promise of and testimony to immortality; and asserted a credal minimalism of belief in Jesus as the Christ without any mention of the Trinity. Yet he never directly attacked the Trinity or satisfaction, and his comments were compatible with a non-essential Trinitarianism or with kinds of Arianism, and with belief in a satisfaction. Locke's *Paraphrase* included one probably anti-Socinian textual explication. His arguments in the *Essay* may have been constructed in part to undercut Trinitarians' extended explanations of the Trinity and, by its final edition, to allow intellectual space for mortalism. These arguments in the *Essay* were, however, compatible with Socinianism rather than definitively Socinian. They could be combined with anti-Socinian views and were epistemological rather than ontological in orientation as observations about the limitations of human understandings of substance, matter, thought and God's power (see Locke, J. §7).

Sociobiology

Following Darwin, biologists and social scientists have periodically been drawn to the theory of natural selection as the source of explanatory insights about human behaviour and social institutions. The combination of Mendelian genetics and Darwinian theory, which did so much to substantiate the theory of evolution in the life sciences, however, has made recurrent adoption of a biological approach to the social sciences controversial. Excesses and errors in social Darwinism, eugenics and mental testing have repeatedly exposed evolutionary approaches in the human sciences to criticism.

Sociobiology is the version of Darwinism in social and behavioural science that became prominent in the last quarter of the twentieth century. Philosophical problems of sociobiology include challenges to the explanatory relevance of Darwinian theory for human behaviour and social institutions, controversies about whether natural selection operates at levels of organization above or below the individual, questions about the meaning of the nature-nurture distinction, and disputes about Darwinism's implications for moral philosophy.

1 Altruism

Sociobiology is a term coined by E.O. Wilson to name that discipline which applies the synthetic theory of evolution - the conjunction of Darwin's claim that nature selects over random variations and the Mendelian theory of genetic inheritance (see Evolution, theory of §1; Darwin, C.R.; Genetics §1) - to explain aspects of and differences in individual behaviour and the behaviour of groups of individuals. Sociobiology seeks to explain behaviour by showing that its emergence is to be expected as a strategy adapted to secure the fitness of the individuals that manifest the behaviour and their genes.

Sociobiology's promise, its explanatory strategy and the controversies surrounding it are aptly illustrated in the discussion of human altruism. Wilson (1976: 3) identified altruism as the 'central' theoretical problem of sociobiology: 'how can altruism, which by definition reduces personal fitness, possibly evolve by natural selection?' Altruism, and cooperation in general, are obvious features of human behaviour. Indeed, sociality requires them. But Wilson (1976: 578) notes that altruism is 'self-destructive behaviour performed for the benefit of others'. Therefore altruism reduces fitness. Accordingly, through evolution it should have been expunged not enhanced. So a characteristic feature of human behaviour appears to be not just exempt from the constraint of natural selection, but perhaps inconsistent with it. Once sociobiologists began to show how natural selection might in fact explain the emergence of altruism as a fitness-maximizing strategy, both its theoretical promise and its interest to philosophers grew rapidly.

The problem of cooperation among humans is one Darwin broached in *The Descent of Man* (1871). His answer to the question of how other-regarding behaviour could evolve made an appeal to the group as the unit of selection. Groups in which members cooperated or otherwise behaved altruistically, are likely in the long run to do better in meeting their members' needs than will groups of egoists. Thus, to the extent that behaviour can be controlled or at least encouraged by individual genetic inheritance, in the struggle for survival between groups, groups of altruists will be selected for. The trouble with this argument is that a group of altruists is vulnerable to 'invasion' by an egoist. Suppose mutation turns a single member of a group of altruists into an egoist who free-rides on the cooperation of others, but does not reciprocate. Note that if altruistic behaviour is genetically fixed, altruists will not retaliate against egoists. The egoist of course does better than the altruists, and amasses more resources. Thus its fitness increases, and it will have more and/or stronger offspring than will the average among altruists. Result: over the long run, the proportion of egoistic descendants will increase, since egoism is a genetically coded mutation that is transmitted down the original mutant's line of descent. After enough generations, there are nothing but egoists left in the original altruistic group.

This argument from individual selection's power to overwhelm group selection had two important consequences: it reinforced evolutionary biologists' commitment to methodological individualism, and it made Darwinism seem irreconcilable with the basic social disposition of altruism. It was W.D. Hamilton (1964), who realized how evolutionary theory and genetics could accommodate altruism, and thus gave sociobiology its late-twentieth-century impetus. Hamilton argued that nature will select for that strategy which leaves the largest number of copies of the gene that codes for it. In the case of sexually reproducing organisms this will usually be

direct offspring - sons and daughters. Whence the altruism of parents to offspring. Moreover, a strategy that sacrifices a son or daughter to save two siblings, three nephews or nieces, or a parent will ensure the survival of just as many or more copies of the individual's genes as would a strategy of saving a son or daughter. Accordingly, nature will select for 'inclusive fitness' which reflects the organisms' fitness and the fitness of each of its kin - the other organisms with whom it shares copies of the same genes, corrected by some coefficient of relatedness. If nature engages in 'kin selection' by selecting for 'inclusive fitness', then, altruism may emerge as an adaptive strategy for an individual that is part of a group of kin.

A problem arises immediately: why does an altruist provide resources at its own expense to unrelated organisms? This question is crucial for sociobiology. As human society evolves it is characterized more and more by cooperation, and less and less by kinship. So, again, either features of human society cannot be accounted for on the basis of selection for the fittest individual strategies, or else sociobiology needs to find another explanation for the emergence of altruism than its inclusive fitness. Sociobiological solutions to this problem have increased its interest for philosophers.

We may hypothesize that altruism emerges as a reciprocal strategy, in which individuals are cooperative in order to secure cooperation from others on later occasions. 'Reciprocal altruism' (the term was introduced by Richard Trivers (1971)) is, however, vulnerable to disappointment in the same way that unconditional altruism is. For the optimal strategy for a fitness maximizer is to accept altruistic pay-offs, but to decline to make them. Accordingly, altruism in the expectation of reciprocation will be displaced by egoism. Trivers and others had noticed that among animals, including humans, the problem of reciprocal altruism reflects what economists have called a 'prisoner's dilemma'. In this setting, the pay-off to free-riding, and the cost of being taken for a sucker, exclude altruism as an available strategy to the rational agent maximizing utility. To the extent that nature selects for maximizing fitness, it will discourage altruism and encourage free-riding whenever the pay-offs in nature are like those in the prisoner's dilemma. (see Decision and game theory §§3, 6). The prisoner's dilemma arises whenever there is a chance to be taken for a sucker combined with an opportunity to free-ride: possible cases include signalling the presence of predators or silently fleeing instead, sharing food or hogging it, encroaching on unprotected territory versus respecting it, procreating without remaining to raise the off-spring. In short, opportunities for altruism by one agent are opportunities for free-riding by another, and it appears that the costs and benefits make the latter an adaptational strategy for individuals and the former a maladaptive one.

However, the prisoner's dilemma is a situation animals face over and over again with a relatively small number of other animals. It is in the search for an optimal strategy for repeated or 'iterated' prisoner's dilemma situations that Hamilton and Axelrod (Axelrod 1984) found a potential solution to Wilson's problem of how altruism emerged. They argued that, under certain circumstances, in iterated prisoner's dilemma encounters, the optimal strategy for the individual is one called 'tit-for-tat': cooperate in game one, and then in each subsequent round do what the other player did in the previous round. Thus, if the other player tries to free-ride in round one, the best response is to refuse to cooperate in round two. If in round two the other party changes strategies and cooperates, in round three one should return to cooperating as well. In the long run no strategy generates a higher pay-off than tit-for-tat. Over the long haul, nature will select fitness maximizers employing this strategy, and as a result cooperation or reciprocal altruism will become fixed in populations. Whence altruism is shown to be compatible with natural selection, and may even have emerged through its operation.

This approach to explaining human behaviour raises issues of philosophical interest: the foundations of rational choice theory, the nature of social conventions, the analysis of teleology.

2 Anthropomorphic and adaptationalist fallacies

Sociobiologists have appeal to fitness-maximizing strategies to explain behaviour like altruism, promiscuity, xenophobia, homosexuality; to explain institutions like the incest taboos, preferential marriage rules, sex role differences, social inequality. Each of these is hypothesized to be the result of natural selection by environmental factors for individual fitness maximization. However, it has seemed absurd to opponents of sociobiology that behaviour which is by definition the result of intentions - desires and beliefs of rather complex sorts - could be intelligibly attributable to nonhumans as far down the phylogenetic ladder as birds and fish. Relatedly, it seems equally absurd to suppose that genes could be causally implicated in the occasions on which such intentions are acted on by humans. Both of these assumptions have been attributed to sociobiology and subjected to

philosophical scrutiny.

The argument runs: ‘altruism’ is defined as action that advantages another with the motive of doing so. It is a concept which carries a definitional commitment to an intentional cause. But this motive forms no part of the sociobiologist’s stipulative definition of fitness, as Wilson, for example, gives it. The term is then employed to explain both human and nonhuman non-intentional dispositions, and is applied to explain human intentional altruism by a gratuitous anthropomorphism of nonhuman dispositions.

Arguments like this are too strong. Few sociobiologists suppose that the occurrences of intentional actions are explainable by natural selection. Their interest in any case is in explaining the emergence of dispositions to behave in certain ways under certain conditions. Such explanations are neutral about the immediately prior causes that trigger the exercise of the dispositions explained. Indeed, if selection works on behaviour as it does on structure, it is likely that it will select a variety of different causes with similar effects, just because these effects have the same selective advantage. In human altruism these causes may include intentional states, while in nonhuman ones it may involve some much simpler mechanism. Sociobiology aims to explain a genus - the disposition to altruism, whether intentional or not, of which the former is a species. Similarly, nature will select not just individual genes, but packages of them, and in fact competing packages of differing genes so long as these have the same or equally adaptive effects in human and infrahuman dispositions. No one supposes that there is a single gene or a small number of genes that code for intentional behaviour of any sort, or even a large number of genes that do more than provide for the disposition to engage in intentional actions of an adaptive sort.

But why suppose that selection operates so pervasively as to make adaptational explanations appropriate? This is a more fundamental challenge to sociobiology. Like other applications of the theory of natural selection, sociobiology has been accused of an obsession with identifying every salient behaviour pattern or institution as the adaptational product of pervasive selection. This commitment to adaptationalism is alleged to reflect an unfalsifiable assumption that deprives sociobiology of its scientific status (see Demarcation problem; Scientific method). Many sociobiologists along with most evolutionary theorists will plead guilty to the charge of adaptationalism, but defend the practice as one demanded by the theory of natural selection. The adaptational imperative of the theory is no different from principles governing hypothesis selection in any other theory. It can be misused to defend the theory come what may, but it can hardly be eschewed altogether in a theory whose aim is to apply Darwinism to the human sciences.

3 The levels of selection

Among evolutionary biologists the notion that species, populations or interbreeding groups could be selected for has been unpopular for reasons sketched out above: such groups are liable to ‘invasion’ by individuals who can take advantage of group traits while not contributing to their maintenance, and group selection is always swamped by individual selection. Some sociobiologists have gone further and argued that not even the individual organism is properly viewed as the level on which selection operates. As G.C. Williams has held, considerations of theoretical parsimony require that adaptational significance should not be accorded to a trait at any level above that necessary to explain the persistence of the trait in question. Following this principle, it has been argued that the locus of selection is always the individual gene - so that if altruism among animals is to be given an evolutionary explanation it must be shown how it can be adaptive for the individual gene borne by the individual altruist (see Genetics §5).

This controversy has drawn philosophers concerned with reductionism into active debates in sociobiology. Genic reductionists argue that attributing purposes or functions in biology is always dangerous, and the risks of anthropomorphism are minimized by restricting their attribution to the lowest level of organization compatible with the evidence: this level is argued to be the individual gene or allele. Holists have argued that some changes at the level of populations cannot be explained by appeal to properties of the individuals or genes themselves.

For instance, given a certain proportion of altruists and egoists in a population, whether the population expands, and how fast are functions of the distribution of altruists and egoists in the subpopulations out of which the whole group is composed. If the structure of the group includes subpopulations in which altruism is heavily represented, then the population as a whole may increase faster than otherwise. But population structure is a group trait, which can be selected for independently of the selection for traits of individual organisms or their particular genes.

Philosophical scrutiny of the claim that the gene is the unique locus of selection has brought sociobiology into contact with fundamental problems in the analysis of probabilistic causation (see Causation §4). Suppose a gene's having a property raises its chances of leaving copies in some contexts but not in others. Then the question arises of how to describe the overall causal power of the trait in all contexts. When we add in the fact that in a structured population of genes, the trait may have probabilistic effects different from those it has when identically but randomly distributed in an unstructured population, the problem of probabilistic causality makes contact with the problem of determining the level of selection.

4 Nature versus nurture

The rise of sociobiology renewed interest in the substantive questions of the relative causal importance of heredity and environment in the distribution of traits. Almost from the first, sociobiology was stigmatized as guilty of 'biological determinism' - the thesis that traits of interest are not subject to human modification because they are genetically fixed. To some extent this charge betrays a fundamental misunderstanding of the synthetic theory of evolution. For Darwinian theory holds that environmental factors select from among hereditary variations; and genetic theory holds that traits - phenotypes - are the product of genetic and environmental factors. Genes alone can fix nothing.

Nevertheless the question remains of how to apportion causal responsibility between environmental and genetic factors. Biologists have done so by linking causality to experimental methods. In an experiment where one can control both environmental variables and the presence or absence of a gene, differences among outcomes enable one to identify the effects of each, and sometimes even apportion the causal responsibility between the environment and the gene. If the presence of a gene has a greater impact on reproductive success than the presence of an environmental factor, then there is some reason to credit it with a predominantly causal role, even though the environmental factor was also causally necessary for any reproduction.

This operational definition of greater or lesser causal responsibility makes it clear that such judgements are always relativized to sets of genes and sets of environmental variables. To say that a trait is mainly under the control of genes will be to make implicit appeal to a range of environmental variables whose presence or absence has lesser effects on the trait's appearance. In other environments, the presence or absence of the same gene may have lesser impact. This difference has led some writers to condemn claims that some traits are innate genetically, or biologically determined, as false or unfounded. For there may always be crucial environmental factors we can almost never vary whose influence on the presence or absence of the trait will be greater than that of the alleged genetic factors.

5 Ideological and moral implications

Some sociobiologists have argued that a Darwinian approach to the evolution of human behaviour can explain the existence of *mores* and moral codes, and the differences among them as the consequence of selection for fitness maximizing over variation in human and prehuman behavioural dispositions. Some writers have gone further (following Herbert Spencer) and have suggested that Darwinian theory might even underwrite or justify some normative claims (see Evolution and ethics).

Few philosophers have expressed sympathy with the latter view, noting that it is a discredited form of naturalism (see Naturalism in ethics §1). Moreover, it has been noted that a theory which purports to explain the moral codes and the social mores which characterize different societies as the result of natural selection can easily become rationalizations for these codes and *mores*, can effectively serve as an intellectual obstacle to changes even when the morals and *mores* are in fact not resistant to fundamental changes in them. Scientists' development of evolutionary explanations for human inequalities and differences can and have been misused to argue that these inequalities are biologically determined, and so cannot be ameliorated or eradicated by environmental intervention. As such, sociobiology can serve an unintended ideological function independent of its cognitive status. Philosophers with differing ideological convictions have sought to uncover the improper ideological exploitation of sociobiological theory.

Sociology of knowledge

Sociologists of knowledge contribute to the enterprise of generating a naturalistic account of knowledge by describing and explaining the observed characteristics of shared cultures. They assume that knowledge can be treated as an object of empirical investigation (rather than mere celebration or condemnation). Because science is understandably taken as our best example of knowledge, the sociology of scientific knowledge plays a pivotal role in the field. It is argued that our natural reasoning capacities, and our sense experience, are necessary but not sufficient conditions for scientific knowledge. Sociologists looking for the causes of its content and style focus on the contribution of conventions and institutions.

The aim of sociologists of knowledge, is to identify such features as (1) the general character of the processes by which new cultural members are ‘socialized’, that is, trained and educated; (2) the specific institutions and authorities charged with this task in particular cases; (3) the mechanisms by which a body of culture is kept relatively stable and hence available for use; (4) the precise circumstances and purposes associated with its employment on particular occasions; (5) the processes by which change is managed and its locus and extent negotiated; (6) the distribution of taken-for-granted beliefs according to status and membership criteria, for example, professional or amateur, male or female, doctor and patient, scientist or technician.

Sociologists emphasize that accepted systems of belief cannot be adequately accounted for by the reasonableness of our individual cognitive faculties, or our sensory experience of the environment. Reason and experience are vital parts of the story of knowledge (social learning and cultural transmission would be unintelligible without them), but they are necessary, not sufficient, conditions. There is always the need to introduce further elements such as the traditional background of practices on which experience impinges, and the highly consequential fact that individuals must make allowances in their calculations for the calculations of others. Individual reason operates in a social context. Furthermore, our individual conclusions and reactions must be coordinated and collectively assessed before they count as knowledge rather than subjective belief, idiosyncrasy or error.

These empirical features are conspicuously visible in scientific culture, hence the central role played by the sociology of scientific knowledge within the general field. This also explains why, wittingly or unwittingly, philosophers of science have done much of the theoretical groundwork for the discipline. In particular they have emphasized that scientific conclusions are under-determined by observational or experimental input, and by the canons of formal logic or the powers of individual reason. Whether it be Duhem’s insight that hypotheses cannot meet the test of experience in isolation, Popper’s insistence on the conjectural character of all knowledge claims, Carnap’s discovery of an infinity of inductive strategies, Kuhn’s highlighting the role of dogmatically accepted paradigms, or Hesse’s (1974) development of a Bayesian approach with its dependence on a negotiable network of shared classifications and prior probabilities, the conclusions all point in the same direction. Scientific knowledge - our best example of knowledge - depends for its structure, stability, content and dynamics on phenomena best identified, and investigated, as social institutions (see Duhem, P.M.M. §4; Carnap, R.; Popper, K.R.; Kuhn, T.S. §2).

Not all philosophical work is relevant in this way. Some gives every appearance of being deliberately fashioned to inhibit naturalistic inquiry. There are philosophers who effectively define ‘rationality’ in terms of its supposed opposition to causality, and particularly social causality. They assume social considerations can only illuminate the general conditions encouraging or discouraging the progress of knowledge, and explain distortions, or deviations from the demands of the scientific method. The task of the sociologist is then confined to explaining, say, the deleterious effect of totalitarian state interference with the freedom of science. This limited agenda may be called the ‘weak programme’ in the sociology of knowledge, in contrast to the ‘strong programme’ suggested by under-determination, which seeks the social dimension to be found in all bodies of knowledge however they are currently evaluated.

Some of the best work in the sociology of knowledge, concentrating on the hardest cases, has been done by historians of science. Ignoring the proscriptions of philosophers who would restrict them to the weak programme, they have provided an abundance of high-quality studies, readable as contributions to the strong programme. These exhibit the problematic, contextual character of the interpretation of experimental findings and, in many cases,

press the argument further and identify plausible causes for the preferences and opinions of the actors involved, for example, contingent commitments to a theory or research method, or the utility the result had for a range of goals and purposes, some of them narrowly professional, others broader and even overtly political. These studies often identify an interest at work. It is important to realize that interests can be generated internally, within the workings of the social system of science itself. The sociology of knowledge carries no prior commitment to what is sometimes called 'externalism', rather than 'internalism', in its methods. The richness of this empirical material precludes summary here, but it spans early Royal Society work on the air pump, the attractions of the corpuscular philosophy, nineteenth-century anatomy and evolutionary theory, cellular biology, geological controversies, non-Euclidean geometry, astronomical discoveries, statistical techniques, genetic theory, and modern particle physics.

Sadly, many of the critical discussions of the sociology of knowledge are blighted by ill-informed and hostile stereotypes. These sustain a number of oft-repeated arguments that are widely taken to discredit the enterprise. For example, the sociology of knowledge is said to be 'self-refuting'. The charge begs the question, because it simply takes for granted the premises of the weak programme: that causal determination equals error or distortion. Again, a distinction is often drawn between the 'context of discovery' and the 'context of justification'. Is not the sociologist concerned with the origin of beliefs, and is that not irrelevant to their epistemological status? In fact, sociologists have little to offer on the origin of ideas, but much to say about their evaluation and subsequent elaboration; so the criticism gets things the wrong way round. Nor, as is often alleged, need the sociology of knowledge derive from, or issue in, a negative stance towards the beliefs under study, as if the only purpose were to 'unmask'. To exhibit, the social construction of science is no more to criticize it than studying the physiology of the eye is to criticize vision.

Sociology, theories of

Throughout the history of sociology, three types of theorizing have co-existed, sometimes uneasily. 'Theories of' provide abstract models of empirical processes; they function both as guides for sociological research and as sources for covering laws whose falsification or validation is intended to provide the basis for a cumulative science. 'Presuppositional studies' abstract away from particular empirical processes, seeking instead to articulate the fundamental properties of social action and order; meta-methodological warrants for the scientific investigation of societies; and normative foundations for moral evaluations of contemporary social life. 'Hermeneutical theory' addresses these basic sociological questions more indirectly, by interpreting the meanings and intentions of classical texts.

The relation between these three forms of theorizing varies historically. In the post-war period, under the institutional and intellectual influence of US sociologists like Parsons and Merton, presuppositional and hermeneutical issues seemed to be settled; 'theories of' proliferated and prospects seemed bright for a cumulative, theoretically-organized science of society. Subsequent social and intellectual developments undermined this brief period of relative consensus. In the midst of the crises of the 1960s and 1970s, presuppositional and hermeneutical studies gained much greater importance, and became increasingly disarticulated from empirical 'theories of'. Confronting the prospect of growing fragmentation, in the late 1970s and early 1980s there appeared a series of ambitious, synthetical works that sought to reground the discipline by providing coherent examples of how the different forms of sociological theory could once again be intertwined. While widely read inside and outside the discipline, these efforts failed in their foundational ambitions.

As a result of this failure, over the last decade sociological theory has had diminishing influence both inside the discipline and without. Inside social science, economic and anthropological theories have been much more influential. In the broader intellectual arena, the most important presuppositional and hermeneutical debates have occurred in philosophy and literary studies. Sociological theorists are now participating in these extra-disciplinary debates even as they have returned to the task of developing 'theories of' particular institutional domains. The future of specifically sociological theory depends on reviving coherent relationships between these different theoretical domains.

1 The forms of sociological theory

Theories of. Following what is taken to be the natural science approach, theorists have produced sets of highly general causal or descriptive propositions aimed at modelling empirical processes (Stinchcombe 1968). These models have had a dual purpose. On the one hand, they are guides to more specific empirical studies of particular social processes. On the other hand, they are designed to produce putative covering laws which such particular empirical studies will falsify or validate.

Max Weber's famous essay on bureaucracy can be viewed as providing a classic example of theorizing along these lines. Weber presented a series of propositions about the structure and processes of bureaucratic authority that has provided the central reference for empirical studies, complementary elaborations, and competing general models in the sociological study of organizations over the last fifty years. In an effort to test the model's insistence on rationality, formal rules and hierarchical command, for example studies emerged that emphasized informal organization and decentralized, problem-oriented decision making; the limited, primarily short-term rationality of bureaucratic action; and even the ceremonial, merely ritualistic qualities of bureaucratic processes. Yet, because Weber's original essay has been accepted as an empirically grounded 'theory of', the field of organizational studies has organized and conceptualized itself as being guided by an accumulative, increasingly elaborated, essentially progressive theoretical model.

While few theoretical models have exercised comparable hegemony, in many empirical sub-fields of sociology one can find 'theories of' that have played similar roles for more limited periods of time.

Presuppositional studies. Rather than developing empirical generalizations to guide studies or provide covering laws, another kind of theoretical effort generalizes away from particular empirical realms to consider fundamental issues that are held to undergird them (Alexander 1982).

Some of these theoretical efforts discuss issues like action and order: is social action practical and goal-oriented or is it normatively guided and oriented by aesthetic, emotional, or moral concerns? Does the patterned nature of social activity derive from controls exercised over individuals by institutions, whether coercive or moral, or does it emerge from pragmatic negotiations between actors as they spontaneously confront the unpredictable contingencies of everyday life?

Some presuppositional studies address more meta-methodological issues: should sociology be modelled after the nomological sciences that aim at producing covering laws and abstract away from the particular and idiographic, or should it be more hermeneutical and aim at producing rich ethnographic interpretations of particular institutions and events?

Other presuppositional studies take the form of critical ideological and moral inquiry: is capitalism an oppressive social system? Is modernity healthy? What are the social obligations of scientists when they are faced with injustice or abuse?

If we consider the relationship of presuppositional studies to the earlier example of bureaucracy, we find an illuminating point of contrast with the ‘theories of’ approach. Rather than arguing on the basis of empirical studies that informal ties exist alongside formal rules, presuppositional theorists have argued that, because emotion is central to action and cooperation basic to order, bureaucratic institutions simply cannot be conceived or explained in the way Weber proposed. Arguing that Weber was, in fact, generalizing from only distinctively Prussian authority structures rather than from bureaucratic organizations as such, other presuppositional theorists have pushed for a case-study approach to organizations in different countries and different historical milieu. Others, focusing on the moral dimension, have condemned both the idea and the practice of bureaucratic organization for ignoring the possibility of democratic self-regulation.

Hermeneutical. ‘Theories of’ and presuppositional studies are highly abstract enterprises, each broaching the question ‘what is society?’ in a direct way. By contrast, the third form of sociological theorizing is not abstracting but idiographic and concrete. Hermeneutical theory seeks to explain human society by explicating, through interpretive argument, the meaning of sociological texts whose consequentiality has given them a classical status (Levine 1995).

These textual efforts are neither historical nor literary. Rather than being primarily directed to questions of intellectual and social context or to questions of genre and aesthetic form, they engage the hermeneutical method to investigate the traditional questions of sociology, albeit in an indirect and idiographic rather than direct and abstracting manner. By reinterpreting canonical texts, hermeneutical readings challenge extant theories and empirical studies that derive their authority from the covering laws or the presuppositions espoused by these classics. By producing new and authoritative versions of canonical texts, the hermeneutical ambition is to re-orient theoretical and empirical practice.

Once again, Weber’s organizational studies provide an illustration. Arguing that Parsons’ translation of Weber’s term, *Herrschaft*, as ‘imperative coordination’ implied that Weber intended a consensual rather than coercive model of authority, hermeneutical theorists have suggested that ‘domination’ is closer to the meaning Weber intended (Roth 1968). This translation challenge has, in fact, been part of the broader theoretical debate between functionalist and conflict-oriented ‘theories of’ various institutional realms (see Functionalism in social science). Within the specific field of organizational studies, hermeneutical students of Weber’s corpus have argued that he envisaged his essay on bureaucracy primarily as a historical and comparative explanation of the development of Western authority structures over time rather than as an effort to model the processes involved in contemporary organizations as such. Making connections to the emphases on charisma and morality in Weber’s other historical studies, these hermeneutical theorists have, indirectly, tried to reframe his original bureaucracy model as one that can incorporate without contradiction the informal, emotional, and normative elements of organizational life.

Very similar kinds of hermeneutical arguments have been made in regard to the classical writings of Marx, Durkheim, and Parsons. Through translations and explications of his earlier writings, Marx has been reinterpreted as being more concerned with the qualitative, cultural, and psychological problems of capitalism than with the quantitative and economic. By exposing the increasing influence of religion in Durkheim’s later and posthumously published work, Durkheim has been reinterpreted as aiming to produce a symbolic rather than morphological

sociology. By emphasizing the disjuncture between the early and the later Parsons, hermeneutical theorists have indirectly argued against systems theory and in support of more pragmatic presuppositions about action and order (see Systems theory in social science §§1-2).

While these three forms of theoretical activity in sociology represent distinct and long-standing traditions, each of them has been the object of polemical challenges from champions of the other types. In practice, however, the three types have often interpenetrated one another. Thus, rather than taking as data only empirical studies, 'theories of' particular institutions have often justified their abstract models by making textual interpretations, challenging or elaborating classical works that earlier sought to explain the same institution. Presuppositional studies, for their part, are often deeply implicated in evaluative statements about the moral worth of different approaches to action and order. Similarly, ideological debates are replete with explanatory claims about the empirical causes and effects of particular institutions.

The classical example of such a blurred genre is Talcott Parsons' *The Structure of Social Action* (1937), perhaps the single most influential theoretical work of post-war sociology. Parsons presented the work primarily as a hermeneutical one, describing it as an investigation of the writings of a group of important European social thinkers, Pareto, Marshall, Durkheim, and Weber. In the lengthy first section of his work, however, Parsons developed a series of highly abstract presuppositional arguments; while ostensibly provided to facilitate his subsequent textual interpretation, this discussion became a fundamental, *sui generis* theoretical argument in itself. Throughout his subsequent exegetical discussions, Parsons also produced pointedly polemical 'theories of', using his textual interpretations to challenge existing empirical models of various institutions.

2 Sociological theory in the post-war world

While the three forms of sociological theorizing have, indeed, always interpenetrated in significant ways, over time there have been remarkable shifts in the relative importance of each genre in the theoretical field. These changes are caused not only by intellectual developments within sociology but also by developments outside of it, by shifts in the intellectual life of society and in the institutions of society itself. These shifts have had significant effects on the relation of sociological theory to theory in other social scientific disciplines and to theoretical efforts in philosophy and aesthetics.

Despite the fundamental and continuing role of theories produced by classical sociological theorists - Marx, Weber, Durkheim, Simmel and Mead - the story line of 'modern' sociological theory begins in 1937 with the publication of Parsons' *The Structure of Social Action*. Despite its intrinsic intellectual power, this blurred genre made virtually no impact at the time. Under the impact of the Great Depression and massive social movements on the Left and Right, US and European sociology was highly fragmented. No single institutional or intellectual centre dominated, and within each sociological community radically divergent theories struggled for recognition. In the wake of the world-historical realignment that followed the Second World War, the social and intellectual situation was fundamentally changed. While European theorizing retained its distinctive forms and practices, the social stability, institutional power, and ideological hegemony of the USA allowed it to emerge as the arbiter of sociology in its professionalized, disciplinary form.

In this new context, Parsons emerged as the dominant theorist of his time. A new generation of sociologists came to consider his (1937) work as having established the canonical foundations of a distinctively modern sociological theory. While this theory was termed 'structural-functionalism', it might more accurately be considered a version of Kantianism (Munch 1981). Rather than using biological models to establish an organicist model of society, Parsons actually devoted his efforts to describing the institutional, psychological, and cultural foundations of differentiated and pluralistic societies that could process economic, political, religious, and ethnic conflicts in democratic, fundamentally cooperative ways (Turner and Holton 1986). Within this Parsonian framework, during the 1950s and early 1960s 'theories of' dominated other types of theoretical practice, and sociology increasingly was viewed as a maturing and cumulative science of society. This optimistic scientism was encouraged by the impression that the post-war explosion of large scale quantitative empirical studies were conducted within the rubric of functionalist thought, an illusion encouraged by the institutionally-oriented, 'middle level' functionalist models of Parsons' discipline (Merton 1967).

Because of its high degree of internal consensus, its cumulative character, and its high degree of intellectual

creativity, in the post-war period US sociological theory achieved a high level of influence, both inside the discipline of sociology and outside. Historians, political scientists, and anthropologists, for example, drew heavily upon the premises of modernization theory, which was the historical foundation of Kantian functionalism. Literary critics drew upon sociological theory to investigate the origins of modern genres. While philosophy remained largely in the analytical mode, more historical and socially-oriented philosophical efforts also drew upon these sociological ideas.

The social and intellectual upheavals that rocked Western societies between the mid 1960s and the 1970s had the effect of displacing not only Kantian functionalism but the approach that emphasized 'theories of'. Pragmatic, phenomenological, and behaviouristic traditions re-emerged as 'micro-sociological theories', powerfully challenging Parsonian theory in various domains (Homans 1961; Garfinkel 1967). Conflict theories and Marxism became increasingly influential, constituting 'macro' challenges to functionalism's optimistic and relatively consensual social models (Collins 1975). As both the models and the canon established by Parsons were put to the test, sociological theorists became increasingly involved in presuppositional and hermeneutical studies (see Pragmatism; Behaviourism in the social sciences).

By the end of the 1970s, Parsons' challengers had triumphed. Sociology was proclaimed a 'multi-paradigmatic' field which, once again, was devoid of either an institutional or theoretical centre. Paradoxically, even as this dramatic sea change reached its climax, the historical context facilitating it dramatically changed. The waves of anti-Establishment protests subsided, backlash movements against them asserted increasing strength, and Western societies began to experience conservative retrenchments. During the same period, state-communist societies began to crumble under their own weight.

These shifts placed sociological theory in a precarious position, even when its prestige was at its greatest height. Responding to the de-centred situation of sociology and to the broader sense of imminent transition in the intellectual and social world at large, the most influential theoretical works that emerged at this time were marked by their refusal to endorse the notion of pluralistic and relativistic social science. To the contrary, these highly ambitious theoretical efforts stepped outside their respective traditions and created grand syntheses (Bourdieu 1977; Giddens 1984; Habermas 1984; Alexander 1982; Collins 1975). Despite marked differences, they had a common aim: to found a new era of intellectual cooperation and social progress in a post-positivistic frame. Indeed, with their combination of hermeneutical, presuppositional, and explanatory ambitions, these efforts closely resembled Parsons' earlier effort to overcome intellectual and social fragmentation in 1937.

But the post-war world that had allowed Parsons' earlier effort to succeed had been dramatically and fundamentally changed. Despite the fact that these ambitiously synthetical works were widely read and admired both inside and outside the discipline of sociology, they turned out to have brought the curtain down on an era rather than ushering in a new one. In a *fin-de-siècle* world torn between deeply pessimistic moods of fragmentation and decline and wildly optimistic hopes of utopian rebirth, none of these synthetic efforts to recreate a new version of Neo-Kantian sociological theory succeeded in gaining hegemony or even in creating traditions that could convincingly establish coherent new lines of theoretical and empirical work.

3 Sociological theory today

The failure of these synthetic efforts, and the continuing impact of the social and intellectual conditions that gave rise to them, has given rise to developments that have had significant repercussions for sociological theory.

Self-identified 'sociological theorists' have been increasingly less able to exert influence over the explanatory models and canonical texts inside the discipline of sociology. Instead, sociological theory is now increasingly viewed merely as one sub-field among many, one devoted to hermeneutical reconstructions of the origins of classical texts, on the one hand, and to 'meta-theoretical' commentaries and arguments about presuppositions, on the other (Ritzer 1992). With the exception of the work of Bourdieu, whose influence, while substantial, remains relatively limited, there exists at present no over-arching general theory that combines hermeneutical and presuppositional arguments with sociological 'theories of' various institutional spheres. While empirical sub-fields continue to be organized theoretically, and the three different types of sociological theorizing flourish within each, these discussions are hermetically cut off from the more generalized theoretical debates in the discipline at large.

Distinctively sociological theories have lost their influence *vis-à-vis* theorizing in other social scientific

disciplines. This is demonstrated by two contradictory developments. The model of society as based upon exchanges between rational actors, derived from economics, has become an international cross-disciplinary tradition that already exercises a deep influence in political science and, increasingly, in sociology (Coleman 1990). At the same time, cultural models of symbolic action and ritual order, which emerged in anthropology (Geertz 1973), have had far-reaching theoretical and empirical effects in history and sociology.

The most influential presuppositional and hermeneutical studies, and even some of the most important theoretical discussions about the nature of contemporary societies (that is, 'theories of'), now occur outside the social sciences in philosophy and literary studies. Under the influence of Michel Foucault and Jacques Derrida, deconstructionism and postmodernism have established an anti-universalist position that has had widespread repercussions throughout Western intellectual life, including the social sciences (Bauman 1995; Seidman 1991). In opposition to this position, Neo-Kantian theorizing about the possibilities for universalism and democracy has been rejuvenated under the influence of John Rawls and Jürgen Habermas (§1) (Cohen and Arato 1992). Between these two poles there have emerged arguments for new forms of pluralistic, identity-based democratic associations, arguments derived from Aristotle, Hegel, and US pragmatism and associated most significantly with the writings of Charles Taylor (§5), Richard Rorty, and Michael Walzer (Boltanski and Thevenot 1991; Warnke 1992).

4 Prospects

In considering the future development of sociological theory, it is important to observe two apparently contradictory developments within the work of those who participated in the creation of synthetic general theories in the 1980s. Leading sociological theorists are now participating in the broader philosophical, political, and literary debates outside of the discipline itself (Calhoun 1992). At the same time, they have also turned towards empirically-focused topics and are developing 'theories of' particular institutional spheres. Only if and when these very different kinds of practices can be brought back together (Mouzelis 1995) will sociological theory regain the coherence, vitality, and intellectual power that allowed it to exercise such wide influence in an earlier day.

Socrates (469-399 BC)

Socrates, an Athenian Greek of the second half of the fifth century BC, wrote no philosophical works but was uniquely influential in the later history of philosophy. His philosophical interests were restricted to ethics and the conduct of life, topics which thereafter became central to philosophy. He discussed these in public places in Athens, sometimes with other prominent intellectuals or political leaders, sometimes with young men, who gathered round him in large numbers, and other admirers. Among these young men was Plato. Socrates' philosophical ideas and - equally important for his philosophical influence - his personality and methods as a 'teacher' were handed on to posterity in the 'dialogues' that several of his friends wrote after his death, depicting such discussions. Only those of Xenophon (Memorabilia,Apology, Symposium) and the early dialogues of Plato survive (for example Euthyphro, Apology, Crito). Later Platonic dialogues such as Phaedo, Symposium and Republic do not present the historical Socrates' ideas; the 'Socrates' appearing in them is a spokesman for Plato's own ideas.

Socrates' discussions took the form of face-to-face interrogations of another person. Most often they concerned the nature of some moral virtue, such as courage or justice. Socrates asked what the respondent thought these qualities of mind and character amounted to, what their value was, how they were acquired. He would then test their ideas for logical consistency with other highly plausible general views about morality and goodness that the respondent also agreed to accept, once Socrates presented them. He succeeded in showing, to his satisfaction and that of the respondent and any bystanders, that the respondent's ideas were not consistent. By this practice of 'elenchus' or refutation he was able to prove that politicians and others who claimed to have 'wisdom' about human affairs in fact lacked it, and to draw attention to at least apparent errors in their thinking. He wanted to encourage them and others to think harder and to improve their ideas about the virtues and about how to conduct a good human life. He never argued directly for ideas of his own, but always questioned those of others. None the less, one can infer, from the questions he asks and his attitudes to the answers he receives, something about his own views.

Socrates was convinced that our souls - where virtues and vices are found - are vastly more important for our lives than our bodies or external circumstances. The quality of our souls determines the character of our lives, for better or for worse, much more than whether we are healthy or sick, or rich or poor. If we are to live well and happily, as he assumed we all want to do more than we want anything else, we must place the highest priority on the care of our souls. That means we must above all want to acquire the virtues, since they perfect our souls and enable them to direct our lives for the better. If only we could know what each of the virtues is we could then make an effort to obtain them. As to the nature of the virtues, Socrates seems to have held quite strict and, from the popular point of view, paradoxical views. Each virtue consists entirely in knowledge, of how it is best to act in some area of life, and why: additional 'emotional' aspects, such as the disciplining of our feelings and desires, he dismissed as of no importance. Weakness of will is not psychologically possible: if you act wrongly or badly, that is due to your ignorance of how you ought to act and why. He thought each of the apparently separate virtues amounts to the same single body of knowledge: the comprehensive knowledge of what is and is not good for a human being. Thus his quest was to acquire this single wisdom: all the particular virtues would follow automatically.

At the age of 70 Socrates was charged before an Athenian popular court with 'impiety' - with not believing in the Olympian gods and corrupting young men through his constant questioning of everything. He was found guilty and condemned to death. Plato's Apology, where Socrates gives a passionate defence of his life and philosophy, is one of the classics of Western literature. For different groups of later Greek philosophers he was the model both of a sceptical inquirer who never claims to know the truth, and of a 'sage' who knows the whole truth about human life and the human good. Among modern philosophers, the interpretations of his innermost meaning given by Montaigne, Hegel, Kierkegaard, and Nietzsche are especially notable.

1 Life and sources

Socrates, an Athenian citizen proud of his devotion to Athens, lived his adult life there engaging in open philosophical discussion and debate on fundamental questions of ethics, politics, religion and education. Going

against the grain of the traditional education, he insisted that personal investigation and reasoned argument, rather than ancestral custom, or appeal to the authority of Homer, Hesiod and other respected poets, was the only proper basis for answering these questions. His emphasis on argument and logic and his opposition to unquestioning acceptance of tradition allied him with such Sophists of a generation earlier as Protagoras, Gorgias and Prodicus, none of whom was an Athenian, but all of whom spent time lecturing and teaching at Athens (see Sophists). Unlike these Sophists Socrates did not formally offer himself or accept pay as a teacher. But many upper-class young Athenian men gathered round him to hear and engage in his discussions, and he had an inspirational and educational effect upon them, heightening their powers of critical thought and encouraging them to take seriously their individual responsibility to think through and decide how to conduct their lives. Many of his contemporaries perceived this education as morally and socially destructive - it certainly involved subverting accepted beliefs - and he was tried in 399 BC before an Athenian popular court and condemned to death on a charge of ‘impiety’: that he did not believe in the Olympian gods, but in new ones instead, and corrupted the young. Scholars sometimes mention specifically political motives of revenge, based on guilt by association: a number of prominent Athenians who were with Socrates as young men or were close friends did turn against the Athenian democracy and collaborated with the Spartans in their victory over Athens in the Peloponnesian war. But an amnesty passed by the restored democracy in 403 BC prohibited prosecution for political offences before that date. The rhetorician Polycrates included Socrates’ responsibility for these political crimes in his *Accusation of Socrates* (see Xenophon, *Memorabilia* I 2.12), a rhetorical exercise written at least five years after Socrates’ death. But there is no evidence that, in contravention of the amnesty, Socrates’ actual accusers covertly attacked him, or his jurors condemned him, on that ground. The defences Plato and Xenophon constructed for Socrates, each in his respective *Apology*, imply that it was his own questioning mind and what was perceived as the bad moral influence he had on his young men that led to his trial and condemnation.

Socrates left no philosophical works, and apparently wrote none. His philosophy and personality were made known to later generations through the dialogues that several of his associates wrote with him as principal speaker (see Socratic dialogues). Only fragments survive of those by Aeschines of Sphettus and Antisthenes, both Athenians, and Phaedo of Elis (after whom Plato’s dialogue *Phaedo* is named). Our own knowledge of Socrates depends primarily on the dialogues of Plato and the Socratic works of the military leader and historian Xenophon. Plato was a young associate of Socrates’ during perhaps the last ten years of his life, and Xenophon knew him during that same period, though he was absent from Athens at the time of Socrates’ death and for several years before and many years after.

We also have secondary evidence from the comic playwright Aristophanes and from Aristotle. Aristotle, although born fifteen years after Socrates’ death, had access through Plato and others to first-hand information about the man and his philosophy. Aristophanes knew Socrates personally; his *Clouds* (first produced *c*.423 BC) pillories the ‘new’ education offered by Sophists and philosophers by showing Socrates at work in a ‘thinkery’, propounding outlandish physical theories and teaching young men how to argue cleverly in defence of their improper behaviour. It is significant that in 423, when Socrates was about 45 years old, he could plausibly be taken as a leading representative in Athens of the ‘new’ education. But one cannot expect a comic play making fun of a whole intellectual movement to contain an authentic account of Socrates’ specific philosophical commitments.

However, the literary genre to which Plato’s and Xenophon’s Socratic works belong (along with the other, lost dialogues) also permits the author much latitude; in his *Poetics* Aristotle counts such works as fictions of a certain kind, alongside epic poems and tragedies. They are by no means records of actual discussions (despite the fact that Xenophon explicitly so represents his). Each author was free to develop his own ideas behind the mask of Socrates, at least within the limits of what his personal experience had led him to believe was Socrates’ basic philosophical and moral outlook. Especially in view of the many inconsistencies between Plato’s and Xenophon’s portraits (see §7 below), it is a difficult question for historical-philosophical interpretation whether the philosophical and moral views the character Socrates puts forward in any of these dialogues can legitimately be attributed to the historical philosopher. The problem of interpretation is made more difficult by the fact that Socrates appears in many of Plato’s dialogues - ones belonging to his middle and later periods (see Plato §§10-16) - discussing and expounding views that we have good reason to believe resulted from Plato’s own philosophical investigations into questions of metaphysics and epistemology, questions that were not entered into at all by the historical Socrates. To resolve this problem - what scholars call the ‘Socratic problem’ - most agree in preferring

Plato to Xenophon as a witness. Xenophon is not thought to have been philosopher enough to have understood Socrates well or to have captured the depth of his views and his personality. As for Plato, most scholars accept only the philosophical interests and procedures, and the moral and philosophical views, of the Socrates of the early dialogues, and, more guardedly, the Socrates of ‘transitional’ ones such as *Meno* and *Gorgias*, as legitimate representations of the historical personage. These dialogues are the ones that predate the emergence of the metaphysical and epistemological inquiries just referred to. However, even Plato’s early dialogues are philosophical works written to further Plato’s own philosophical interests. That could produce distortions, also; and Xenophon’s relative philosophical innocence could make his portrait in some respects more reliable. Moreover, it is possible, even probable, that in his efforts to help his young men improve themselves Socrates spoke differently to the philosophically more promising ones among them - including Plato - from the way he spoke to others, for example Xenophon. Both portraits could be true, but partial and needing to be combined (see §7). The account of Socrates’ philosophy given below follows Plato, with caution, while giving independent weight also to Xenophon and to Aristotle.

2 Life and sources (cont.)

Xenophon’s *Apology* of Socrates, *Symposium* and *Memorabilia* (or *Memoirs*) may well reflect knowledge of Plato’s own *Apology* and some of his early and middle period dialogues, as well as lost dialogues of Antisthenes and others. Xenophon composed the *Memorabilia* over many years, beginning only some ten years after Socrates’ death, avowedly in order to defend Socrates’ reputation as a good man, a true Athenian gentleman, and a good influence upon his young men. The same intention motivated his*Apology* and *Symposium*. Anything these works contain about Socrates’ philosophical opinions and procedures is ancillary to that apologetic purpose. Plato’s *Apology*, of course, is similarly apologetic, but it and his other early dialogues are carefully constructed discussions, strongly focused upon questions of philosophical substance. Plato evidently thought Socrates’ philosophical ideas and methods were central to his life and to his mission. Xenophon’s and Plato’s testimony are agreed that Socrates’ discussions consistently concerned the *aretai*, the recognized ‘virtues’ or excellences of character (see Aretē), such as justice, piety, self-control or moderation (*sōphrosynē*), courage and wisdom; what these individual characteristics consist in and require of a person, what their value is, and how they are acquired, whether by teaching or in some other way. In his *Apology* and elsewhere Plato has Socrates insist that these discussions were always inquiries, efforts made to engage his fellow-discussants in coming jointly to an adequate understanding of the matters inquired into. He does not himself know, and therefore cannot teach anyone else - whether by means of these discussions or in some other way - either how to be virtuous or what virtue in general or any particular virtue is. Furthermore, given his general characterization of virtue (see §§4-5), Plato’s Socrates makes a point of suggesting the impossibility in principle of teaching virtue at all, by contrast with the Sophists who declared they could teach it. Virtue was not a matter of information about living or rote techniques of some sort to be handed on from teacher to pupil, but required an open-ended personal understanding that individuals could only come to for themselves. Xenophon, too, reports that Socrates denied he was a teacher of *aretē*, but he pays no attention to such issues of philosophical principle. He does not hesitate to show Socrates speaking of himself as a teacher (see *Apology* 26, *Memorabilia* I 6.13-14), and describes him as accepting young men from their fathers as his pupils (but not for a fee), and teaching them the virtues by displaying his own virtues to them for emulation, as well as through conversation and precepts. Perhaps Socrates did not insist on holding to strict philosophical principles in dealing with people on whom their point would have been lost.

In his *Apology* Plato’s Socrates traces his practice of spending his days discussing and inquiring about virtue to an oracle delivered at the shrine of Apollo at Delphi. Xenophon also mentions this oracle in his *Apology*. A friend of Socrates’, Chaerephon, had asked the god whether anyone was wiser than Socrates; the priestess answered that no one was. Because he was sure he was not wise at all - only the gods, he suspected, could actually *know* how a human life ought to be led - Socrates cross-examined others at Athens with reputations for that kind of wisdom. He wanted to show that there were people wiser than he and thus discover the true meaning of the oracle - Apollo was known to speak in riddles requiring interpretation to reach their deeper meaning. In the event, it turned out that the people he examined were not wise, since they could not even give a self-consistent set of answers to his questions: obviously, true knowledge requires at least that one think and speak consistently on the subjects one professes to know. So he concluded that the priestess’s reply had meant that of all those with reputations for wisdom only he came close to deserving it; he wisely did not profess to know these things that only gods can know, and that was

wisdom enough for a human being. Because only he knew that he did *not* know, only he was ready earnestly to inquire into virtue and the other ingredients of the human good, in an effort to learn. He understood therefore that Apollo's true intention in the oracle had been to encourage him to continue his inquiries, to help others to realize that it is beyond human powers actually to *know* how to live - that is the prerogative of the gods - and to do his best to understand as far as a human being can how one ought to live. The life of philosophy, as led by him, was therefore something he was effectively ordered by Apollo to undertake.

We must remember that Socrates was on trial on a charge of 'impiety'. In tracing his philosophical vocation back to Apollo's oracle, and linking it to a humble recognition of human weakness and divine perfection, he was constructing a powerful rebuttal of the charges brought against him. But it cannot be literally true - if that is what he intended to say - that Socrates began his inquiries about virtue only after hearing of the oracle. Chaerephon's question to Apollo shows he had established a reputation in Athens for wisdom before that. That reputation cannot have rested on philosophical inquiries of another sort. In Plato's *Phaedo* Socrates says he had been interested as a young man in philosophical speculations about the structure and causes of the natural world, but he plainly did not take those interests very far; and in any event, his reputation was not for that kind of wisdom, but wisdom about how to lead a human life. In fact we do not hear of the duty to Apollo in Xenophon, or in other dialogues of Plato, where we might expect to find it if from the beginning Socrates thought Apollo had commanded his life of philosophizing. However, we need not think Socrates was false to the essential spirit of philosophy as he practised it if in looking back on his life under threat of condemnation for impiety he chose, inaccurately, to see it as initially imposed on him by Apollo's oracle.

Despite its impressiveness, Socrates' speech failed to convince his jury of 501 male fellow citizens, and he died in the state prison by drinking hemlock as required by law. His speech evidently offended the majority of the jurors by its disdain for the charges and the proceedings; Xenophon explains his lofty behaviour, which he thinks would otherwise have been lunatic - and damaging to his reputation - by reporting that he had told friends in advance that as a 70-year-old still in possession of his health and faculties it was time for him to die anyhow, before senility set in. Furthermore, his 'divine sign' - the 'voice' he sometimes heard warning him for his own good against a contemplated course of action - had prevented him from spending time crafting a defence speech. (This voice seems to have been the basis for the charge of introducing 'new' gods.) So he would do nothing to soften his manner in order to win his freedom. Even if this story is true, Plato could be right that Socrates put on a spirited, deeply serious defence of his life and beliefs - one that he thought should have convinced the jurors of his innocence, if only they had judged him intelligently and fairly.

3 Socratic elenchus, or refutation

In cross-examining those with reputations for wisdom about human affairs and showing their lack of it, Socrates employed a special method of dialectical argument that he himself had perfected, the method of 'elenchus' - Greek for 'putting to the test' or 'refutation'. He gives an example at his trial when he cross-examines Meletus, one of his accusers (Plato, *Apology* 24d-27e). The respondent states a thesis, as something he *knows* to be true because he is wise about the matter in question. Socrates then asks questions, eliciting clarifications, qualifications and extensions of the thesis, and seeking further opinions of the respondent on related matters. He then argues, and the respondent sees no way not to grant, that the original thesis is logically inconsistent with something affirmed in these further responses. For Socrates, it follows at once that the respondent did not know what he was talking about in stating his original thesis: true knowledge would prevent one from such self-contradiction. So the respondent suffers a personal set-back; *he* is refuted - revealed as incompetent. Meletus, for example, does not have consistent ideas about the gods or what would show someone not to believe in them, and he does not have consistent ideas about who corrupts the young, and how; so he does not know what he is talking about, and no one should take *his* word for it that Socrates disbelieves in the gods or has corrupted his young men. In many of his early dialogues Plato shows Socrates using this method to examine the opinions of persons who claim to be wise in some matter: the religious expert Euthyphro on piety (*Euthyphro*), the generals Laches and Nicias on courage (*Laches*), the Sophist Protagoras on the distinctions among the virtues and whether virtue can be taught (*Protagoras*), the rhapsodist Ion on what is involved in knowing poetry (*Ion*), the budding politician Alcibiades on justice and other political values (*Alcibiades*), the Sophist Hippias on which was the better man, Odysseus or Achilles (*Lesser Hippias*), and on the nature of moral and aesthetic beauty (*Greater Hippias*). They are all refuted - shown to have mutually inconsistent ideas on the subject discussed (see Plato §§4, 6, 8-9).

But Socrates is not content merely to demonstrate his interlocutor's lack of wisdom or knowledge. That might humiliate him into inquiring further or seeking by some other means the knowledge he has been shown to lack, instead of remaining puffed up with self-conceit. That would be a good thing. But Socrates often also indicates clearly that his cross-examination justifies him and the interlocutor in rejecting as false the interlocutor's original thesis. Logically, that is obviously wrong: if the interlocutor contradicts himself, at least one of the things he has said must be false (indeed, all of them could be), but the fact alone of self-contradiction does not show where the falsehood resides. For example, when Socrates leads Euthyphro to accept ideas that contradict his own definition of the pious as whatever pleases all the gods, Socrates concludes that that definition has been shown to be false (*Euthyphro* 10d-11a), and asks Euthyphro to come up with another one. He does not usually seem to consider that perhaps on further thought the additional ideas would seem faulty and so merit rejection instead.

Socrates uses his elenctic method also in discussion with persons who are not puffed up with false pride, and are quite willing to admit their ignorance and to reason out the truth about these important matters. Examples are his discussions with his long-time friend Crito on whether he should escape prison and set aside the court's death sentence (Plato, *Crito*), and with the young men Charmides, on self-control (*Charmides*), and Lysis and Menexenus, on the nature of friendship (*Lysis*). Socrates examines Crito's proposal that he escape on the basis of principles that he presents to him for his approval, and he, together with Crito (however half-heartedly), rejects it when it fails to be consistent with them. And he examines the young men's successive ideas about these virtues, rejecting some of them and refining others, by relying on their own acceptance of further ideas that he puts to them. Again, he is confident that the inconsistencies brought to light in their ideas indicate the inadequacy of their successive proposals as to the nature of the moral virtue in question.

In many of his discussions, both with young men and the allegedly wise, Socrates seeks to know what some morally valuable property is - for example, piety, courage, self-control or friendship (see §5). Rejecting the idea that one could learn this simply from attending to examples, he insisted on an articulated 'definition' of the item in question - some *single* account that would capture all at once the presumed common feature that would entitle anything to count as a legitimate instance. Such a definition, providing the essence of the thing defined, would give us a 'model' or 'paradigm' to use in judging whether or not some proposed action or person possesses the moral value so defined (*Euthyphro* 6d-e). Aristotle says (in *Metaphysics* I, 6) that Socrates was the first to interest himself in such 'universal definitions', and traces to his interest in them Plato's first impetus towards a theory of Forms, or 'separated' universals (see Plato §10).

In none of his discussions in Plato's early works does Socrates profess to think an adequate final result has actually been established - about the nature of friendship, or self-control, or piety, or any of the other matters he inquires about. Indeed, on the contrary, these works regularly end with professions of profound ignorance about the matter under investigation. Knowledge is never attained, and further questions always remain to be considered. But Socrates does plainly think that progress towards reaching final understanding has taken place (even if only a god, and no human being, could ever actually attain it). Not only has one discovered some things that are definitely wrong to say; one has also achieved some positive insights that are worth holding onto in seeking further systematic understanding. Given that Socrates' method of discussion is elenctic throughout, what does he think justifies this optimism?

On balance, our evidence suggests that Socrates had worked out no elaborate theory to support him here. The ideas he was stimulated to propound in an elenctic examination which went against some initial thesis seemed to him, and usually also to the others present, so plausible, and so supportable by further considerations, that he and they felt content to reject the initial thesis. Until someone came up with arguments to neutralize their force, it seemed the thesis was doomed, as contrary to reason itself. Occasionally Socrates expresses himself in just those terms: however unpalatable the option might seem, it remains open to someone to challenge the grounds on which his conclusions rest (see *Euthyphro* 15c, *Gorgias* 461d-462a, 509a, *Crito* 54d). But until they do, he is satisfied to treat his and his interlocutor's agreement as a firm basis for thought and action. Later, when Plato himself became interested in questions of philosophical methodology in his *Meno*, this came to seem a philosophically unsatisfactory position; Plato's demand for justification for one's beliefs independent of what seemed on reflection most plausible led him to epistemological and metaphysical inquiries that went well beyond the self-imposed restriction of Socratic philosophy to ethical thought in the broadest sense. But Socrates did not raise these questions. In this respect more bound by traditional views than Plato, he had great implicit confidence in his and

his interlocutors' capacity, after disciplined dialectical examination of the issues, to reach firm ground for constructing positive ideas about the virtues and about how best to lead a human life - even if these ideas never received the sort of final validation that a god, understanding fully the truth about human life, could give them.

4 Elenchus and moral progress

The topics Socrates discussed were always ethical, and never included questions of physical theory or metaphysics or other branches of philosophical study. Moreover, he always conducted his discussions not as theoretical inquiries but as profoundly personal moral tests. Questioner and interlocutor were equally putting their ways of life to what Socrates thought was the most important test of all - their capacity to stand up to scrutiny in rational argument about how one ought to live. In speaking about human life, he wanted his respondents to indicate what they truly believed, and as questioner he was prepared to do the same, at least at crucial junctures. Those beliefs were assumed to express not theoretical ideas, but the very ones on which they themselves were conducting their lives. In losing an argument with Socrates you did not merely show yourself logically or argumentatively deficient, but also put into question the very basis on which you were living. Your way of life might ultimately prove defensible, but if you cannot now defend it successfully, you are not leading it *with* any such justification. In that case, according to Socrates' views, your way of life is morally deficient. Thus if Menexenus, Lysis and Socrates profess to value friendship among the most important things in life and profess to be one another's friends, but cannot satisfactorily explain under pressure of elenctic investigation what a friend is, that casts serious doubt on the quality of any 'friendship' they might form (Plato, *Lysis* 212a, 223b). Moral consistency and personal integrity, and not mere delight in argument and logical thought, should therefore lead you to repeated elenctic examination of your views, in an effort to render them coherent and at the same time defensible on all sides through appeal to plausible arguments. Or, if some of your views have been shown false, by conflicting with extremely plausible general principles, it behoves you to drop them - and so to cease living in a way that depends upon accepting them. In this way, philosophical inquiry via the elenchus is fundamentally a personal moral quest. It is a quest not just to understand adequately the basis on which one is actually living, and the personal and moral commitments that this contains. It is also a quest to change the way one lives as the results of argument show one ought to, so that, at the logical limit of inquiry, one's way of life would be completely vindicated. Accordingly, Socrates in Plato's dialogues regularly insists on the individual and personal character of his discussions. He wants to hear the views of the one person with whom he is speaking. He dismisses as of no interest what outsiders or most people may think - provided that is not what his discussant is personally convinced is true. The views of 'the many' may well not rest on thought or argument at all. Socrates insists that his discussant shoulder the responsibility to explain and defend rationally the views he holds, and follow the argument - reason - wherever it may lead.

We learn a good deal about Socrates' own principles from both Plato and Xenophon. Those were ones that had stood up well over a lifetime of frequent elenctic discussions and had, as he thought, a wealth of plausible arguments in their favour. Foremost is his conviction that the virtues - self-control, courage, justice, piety, wisdom and related qualities of mind and soul - are essential if anyone is to lead a good and happy life. They are good in themselves for a human being, and they guarantee a happy life, *eudaimonia* - something that he thought all human beings always wanted, and wanted more than anything else. The virtues belong to the soul - they are the condition of a soul that has been properly cared for and brought to its best state. The soul is vastly more important for happiness than are health and strength of the body or social and political power, wealth and other external circumstances of life; the goods of the soul, and pre-eminently the virtues, are worth far more than any quantity of bodily or external goods. Socrates seems to have thought these other goods *are* truly good, but they only *do* people good, and thereby contribute to their happiness, under the condition that they are chosen and used in accordance with virtues indwelling in their souls (see Plato, *Apology* 30b, *Euthydemus* 280d-282d, *Meno* 87d-89a).

More specific principles followed. Doing injustice is worse for oneself than being subjected to it (*Gorgias* 469c-522e): by acting unjustly you make your soul worse, and that affects for the worse the whole of your life, whereas one who treats you unjustly at most harms your body or your possessions but leaves your soul unaffected. On the same ground Socrates firmly rejected the deeply entrenched Greek precept to aid one's friends and harm one's enemies, and the accompanying principle of retaliation, which he equated with returning wrongs for wrongs done to oneself and one's friends (*Crito* 49a-d). Socrates' daily life gave witness to his principles. He was poor, shabbily dressed and unshod, and made do with whatever ordinary food came his way: such things matter little. Wealth, finery and delicacies for the palate are not worth panting after and exerting oneself to enjoy. However,

Socrates was fully capable of relishing both refined and plain enjoyments as occasion warranted (see §7).

5 The unity of virtue

The Greeks recognized a series of specially prized qualities of mind and character as *aretai* or virtues. Each was regarded as a distinct, separate quality: justice was one thing, concerned with treating other people fairly, courage quite another, showing itself in vigorous, correct behaviour in circumstances that normally cause people to be afraid; and self-control or moderation, piety and wisdom were yet others. Each of these ensured that its possessor would act in some specific ways, regularly and reliably over their lifetime, having the justified conviction that those are ways one *ought* to act - *agathon* (good) and *kalon* (fine, noble, admirable or beautiful) ways of acting. But each type of virtuous person acts rightly and well not only in regularly recurring, but also in unusual and unheralded, circumstances; the virtue involves always getting something right about how to live a good human life. Socrates thought these virtues were essential if one was to live happily (see §4). But what exactly were they? What was it about someone that made them just, or courageous, or wise? If you did not know that, you would not know what to do in order to acquire those qualities. Furthermore, supposing you did possess a virtue, you would have to be able to explain and defend by argument the consequent ways in which you lived - otherwise your conviction that those are ways one *ought* to act would be shallow and unjustified. And in order to do that you would have to know what state of mind the virtue was, since that is essential to them (see Plato, *Charmides* 158e-159a). Consequently, in his discussions Socrates constantly asked for ‘definitions’ of various virtues: what is courage (*Laches*); what is self-control or moderation (*Charmides*), what is friendship (*Lysis*) and what is piety (*Euthyphro*). As this context shows, he was asking not for a ‘dictionary definition’, an account of the accepted linguistic understanding of a term, but for an ethically defensible account of an actual condition of mind or character to which the word in common use would be correctly applied. In later terminology, he was seeking a ‘real’ rather than a ‘nominal’ definition (see Definition; Plato §§6-9).

Socrates objected to definitions that make a virtue some external aspect of a virtuous action (such as the manner in which it is done - for example its ‘quiet’ or measured quality in the case of moderation, *Charmides* 160b-d), or simply the doing of specific types of action, described in terms of their external circumstances (such as, for courage, standing one’s ground in battle; *Laches* 190e-191d). He also objected to more psychological definitions that located a virtue in some non-rational and non-cognitive aspect of the soul (for example, in the case of courage, the soul’s endurance or strength of resistance) (*Laches* 192d-193e). For his own part, he regularly shows himself ready to accept only definitions that identify a virtue with some sort of knowledge or wisdom about what is valuable for a human being. That ‘intellectualist’ expectation about the nature of virtue, although never worked out to his satisfaction in any Platonic dialogue, is central to Socrates’ philosophy.

Given that in his discussions he is always the questioner, probing the opinions of his respondent and not arguing for views of his own, we never find Socrates stating clearly what led him to this intellectualism. Probably, however, it was considerations drawn from the generally agreed premise that each virtue is a condition motivating certain voluntary actions, chosen because they are good and fine or noble. He took it that what lies behind and produces any voluntary action is the idea under which it is done, the conception of the action in the agent’s mind that makes it seem the thing to do just then. If so, each virtue must be some state of the mind, the possessor of which constantly has certain distinctive general ideas about how one ought to behave. Furthermore, since virtues get this *right*, these are true ideas. And since a virtuous person acts well and correctly in a *perfectly reliable* way, they must be seated so deeply in the mind as to be ineradicable and unwaveringly present. The only state of mind that meets these conditions is knowledge: to know a subject is not just to be thoroughly convinced, but to have a deep, fully articulated understanding, being ready with explanations to fend off objections and apparent difficulties and to extend old principles into new situations, and being prepared to show with the full weight of reason precisely why each thing falling under it is and must be so. Each virtue, then, must be knowledge about how one ought to behave in some area of life, and why - a knowledge so deep and rationally secure that those who have it can be counted upon never to change their minds, never to be argued out of or otherwise persuaded away from, or to waver in, their conviction about how to act.

In Plato’s *Protagoras* Socrates goes beyond this, and identifies himself with the position, rejected by Protagoras in their discussion, that the apparently separate virtues of justice, piety, self-control, courage and wisdom are somehow one and the same thing - some single knowledge (361a-b). Xenophon too confirms that Socrates held

this view (*Memorabilia* III 9.5). Protagoras defends the position that each of the virtues is not only a distinct thing from each of the others, but so different in kind that a person could possess one of them without possessing the others (329d-e). In opposing him, Socrates sometimes speaks plainly of two allegedly distinct virtues being ‘one’ (333b). Given this unity of the virtues, it would follow that a person could not possess one without having them all. And in speaking of justice and piety in particular, Socrates seems to go further, to imply that every action produced by virtue is equally an instance of *all* the standardly recognized virtues: pious as well as just, wise and self-controlled and courageous also. Among his early dialogues, however, Plato’s own philosophical interests show themselves particularly heavily in the *Protagoras*, so it is doubtful how far the details of his arguments are to be attributed to the historical Socrates. The issues raised by Socrates in the *Protagoras* were, none the less, vigorously pursued by subsequent ‘Socratic’ philosophers (as Plutarch’s report in *On Moral Virtue* 2 demonstrates). And the positions apparently adopted by Plato’s Socrates were taken up and ingeniously defended by the Stoic philosopher Chrysippus (see Stoicism §16). As usual, because of his questioner’s role, it is difficult to work out Socrates’ grounds for holding to the unity of virtue; and it is difficult to tell whether, and if so how, he allowed that despite this unity there were some real differences between, say, justice and self-control, or courage and piety. Apparently he thought the same body of knowledge - knowledge of the whole of what is and is not good for human beings, and why it is so or not - must at least underlie the allegedly separate virtues. If you did not have that vast, comprehensive knowledge you could not be in the state of mind which is justice or in that which is courage, and so on; and if you did have it you would necessarily be in those states of mind. It seems doubtful whether Socrates himself progressed beyond that point. Efforts to do that were made by Chrysippus and the other philosophers referred to above. And despite denying that all virtues consist in knowledge, Plato in the *Republic* and Aristotle in *Nicomachean Ethics* VI follow Socrates to the extent of holding, in different ways, that you need to have all the virtues in order to have any one.

6 Weakness of will denied

In Plato’s *Protagoras* Socrates also denies the possibility of weakness of will - being ‘mastered’ by some desire so as to act voluntarily in a way one knows is wrong or bad (see also Xenophon, *Memorabilia* III 9.4, IV 5.6.) All voluntary wrongdoing or bad action is due to ignorance of how one ought to act and why, and to nothing else. This would be easy to understand if Socrates were using ‘knowing’ quite strictly, to refer to the elevated and demanding sort of knowledge described in §5 (sometimes called ‘Socratic knowledge’). Someone could know an action was wrong or bad, with full ‘Socratic knowledge’, only if they were not just thoroughly convinced, but had a deep, fully articulated understanding, being ready with explanations to fend off objections and apparent difficulties, and prepared to show precisely *why* it was so. That would mean that these ideas were seated so deeply in the mind as to be ineradicable and unwaveringly present. Accordingly, a person with ‘Socratic knowledge’ could not come to hold even momentarily that the action in question would be the thing to do, and so they could never do it voluntarily.

However, Plato’s Socrates goes further. He explains his denial of weak-willed action by saying that a person cannot voluntarily do actions which, in doing them, they even *believe* to be a wrong or bad thing to do (*Protagoras* 358c-e). He gives a much-discussed, elaborate argument to establish this stronger conclusion, starting from assumptions identifying that which is pleasant with that which is good (352a-357e). These assumptions, however, he attributes only to ordinary people, the ones who say they believe in the possibility of weak-willed action; he makes it clear to the careful reader, if not to Protagoras, that his own view is simply that pleasure is a good thing, not ‘the’ good (351c-e; see 354b-d). Although some scholars have thought otherwise, Socrates himself does not adopt a hedonist analysis of the good in the *Protagoras* or elsewhere either in Plato or Xenophon; indeed, he speaks elsewhere against hedonist views (see Hedonism). The fundamental principle underlying his argument - a principle he thinks ordinary people will accept - is that voluntary action is always ‘subjectively’ rational, in the sense that an agent who acts to achieve some particular sort of value always acts with the idea that what they are doing achieves *more* of that value than alternatives then thought by them to be available would achieve. If someone performs an overall bad action because of some (lesser) good they think they will get from it, they cannot do it while *believing* it is bad overall. That would mean they thought they could have got *more* good by refraining, and their action would violate the principle just stated. Instead, at the time they acted (despite what they may have thought before or after acting), they believed (wrongly and ignorantly) that the action would be good overall for them to do. Thus ignorance, and only ignorance, is responsible for voluntary error. Weakness of will - knowingly

pursuing the worse outcome - is psychologically impossible: ‘No one does wrong willingly’.

The details of this argument may not represent explicit commitments of the historical Socrates. None the less, his denial of weakness of will, understood as presented in Plato’s *Protagoras*, was the centre of a protracted debate in later times. First Plato himself, in *Republic* IV, then Aristotle in *Nicomachean Ethics* VII, argued against Socrates’ conclusion, on the ground that he had overlooked the fact that human beings have other sources of motivation that can produce voluntary actions, besides their ideas about what is good or bad, or right or wrong to do. ‘Appetites’ and ‘spirited desires’ exist also, which can lead a person to act in fulfilment of them without having to adopt the idea, in their beliefs about what is best to do, that so acting would be a good thing (see Plato §14; Aristotle §20, 22-23). The Stoics, however, and especially Chrysippus, argued vigorously and ingeniously in defence of Socrates’ analysis and against the Platonic-Aristotelian assumption of alternative sources of motivation that produce voluntary action on their own (see Stoicism §19). In fact, during Hellenistic times it was the Socratic, ‘unitary’ psychology of action that carried the day; the Platonic-Aristotelian alternative, dominant in the ‘common sense’ and the philosophy of modern times, was a minority view. The issues Socrates raised about weakness of will continue to be debated today.

7 Socrates’ personality

Socrates drew to himself many of the brightest and most prominent people in Athens, securing their fascinated attention and their passionate friendship and support. His effectiveness as a philosopher, and the Socratic ‘legend’ itself, depended as much on the strength and interest of his personality as on the power of his mind. Plato’s and Xenophon’s portraits of Socrates as a person differ significantly, however. Plato’s Socrates is aloof and often speaks ironically, although also with unusual and deeply held moral convictions; paradoxically, the depth and clarity of his convictions, maintained alongside the firm disclaimer to know what was true, could seem all the stronger testimony to their truth, and made them felt the more strongly as a rebuke to the superficiality of one’s own way of living. In Xenophon, Socrates is also sometimes ironical and playful, especially in the *Symposium*, but his conversation is usually direct, even didactic, and often chummy in tone; his attitudes are for the most part conventional though earnest; and there is nothing to unsettle anyone or make them suspect hidden depths. It is much easier to believe that the Socrates of Plato’s dialogues could have had such profound effects on the lives of the brightest of his contemporaries than did the character in Xenophon. That is one reason given for trusting Plato’s more than Xenophon’s portrait of the historical personage. But perhaps Socrates used the more kindly and genial manner and conventional approach depicted by Xenophon to draw out the best in some of his young men and his friends - ones who would have been put off by the Platonic subtleties. The historical Socrates may have been a more complex person than even Plato presents.

Plato and Xenophon both represent Socrates as strongly attracted to good-looking young men in the ‘bloom’ of their middle to late teens, just the period when they were also coming of age morally and intellectually. In both he speaks of himself as unusually ‘erotic’ by temperament and constantly ‘in love’. But he explains his ‘erotic’ attachments in terms of his desire to converse with bright and serious young men, to question them about virtue and how best to live a human life, and to draw out what was best in their minds and characters. In Xenophon he describes his love as love for their souls, not their bodies, and he vigorously condemns sexual relations with any young man: using him that way disgraces him and harms him by encouraging a loose attitude as regards physical pleasures *Symposium* 8). The overheated sexuality of Plato’s own accounts (*Symposium* and *Phaedrus*) of *erōs*, sexual love, for a young man’s beauty as motivating an adult male to pursue philosophical truth into an eternal realm of Forms (see Plato §12) is to be distinguished sharply from Socrates’ ideas, as we can gather them from Xenophon and from Plato’s own early dialogues.

Xenophon emphasizes Socrates’ freedom from the strong appetites for food, drink, sex and physical comfort that dominate other people; his *enkrateia* or self-mastery is the first of the virtues that Xenophon claims for him (*Memorabilia* I 2.1). He was notorious for going barefoot even in winter and dressing always in a simple cloak. Socrates’ self-mastery was at the centre of Antisthenes’ portrayal, and is reflected also in several incidents reported in Plato, such as his serene dismissal of the young Alcibiades’ efforts to seduce him sexually (Plato, *Symposium* 217b-219e), or, perhaps when engrossed in a philosophical problem, his standing in the open (during a break in the action while on military service) from morning to night, totally indifferent to everything around him (*Symposium* 220c-d). This ‘ascetic’ Socrates, especially as presented by Antisthenes - rejecting conventional

comforts and conventional behaviour - became an inspiration for the 'Cynics' of later centuries (see Cynics).

8 Socrates in the history of philosophy

Looking back on the early history of philosophy, later philosophers traced to Socrates a major turn in its development. As Cicero puts it: 'Socrates was the first to call philosophy down from the heavens… and compel it to ask questions about life and morality' (*Tusculan Disputations* V 10-11). Previously it had been concerned with the origins and nature of the physical world and the explanation of celestial and other natural phenomena. Modern scholarship follows the ancients' lead in referring standardly to philosophers before Socrates collectively as 'Presocratics' (see Presocratic philosophy). This includes Democritus, in fact a slightly younger contemporary of Socrates; Cicero's verdict needs adjustment, in that Democritus, independently of Socrates, also investigated questions about ethics and morality. With the sole exception of Epicureanism, which developed separately out of Democritean origins, all the major movements of Greek philosophy after Socrates had roots in his teaching and example. This obviously applies to Plato, whose philosophical development began with a thorough reworking and assimilation of Socratic moral inquiry, and through him to Aristotle and his fellow members of Plato's Academy, Speusippus and Xenocrates and others, as well as to later Platonists. Among Socrates' inner circle were also Aristippus of Cyrene, who founded the hedonist Cyrenaic school (see Aristippus the Elder; Cyrenaics), and Antisthenes, an older rival of Plato's and major teacher in Athens of philosophical dialectic. Both of these figure in Xenophon's *Memorabilia* (Antisthenes also in his *Symposium*), where they are vividly characterized in conversation with Socrates. Another Socratic, Euclides, founded the Megarian school (see Megarian school). These 'Socratic schools' developed different themes already prominent in Socrates' own investigations, and competed in the claim to be his true philosophical heirs (see Socratic schools; Dialectical School).

In the third to first centuries BC, both the Stoics and their rivals the Academic sceptics claimed to be carrying forward the Socratic tradition. In both cases this was based upon a reading of Plato's dialogues and perhaps other eye-witness reconstructions of Socrates' philosophy. The Academic Arcesilaus interpreted the Platonic Socrates as a sceptical inquirer, avidly searching but never satisfied that the truth on any disputed question had been finally uncovered. He could point to much about Plato's Socrates in support: his modest but firm denial that he possessed any knowledge, and his constant practice of inquiring into the truth by examining others' opinions on the basis of ideas which they themselves accepted, without formally committing himself to these ideas even when he was the one to first suggest them. Arcesilaus, however, applied his sceptical Socratic dialectic to more than the questions of ethics and human life about which Socrates himself had argued, making it cover the whole range of philosophical topics being investigated in his day. The Stoics read the dialogues (especially the *Euthydemus* and *Protagoras*) quite differently. They found Socrates espousing a complete doctrine of ethics and the psychology of human action. He posed his questions on the basis of this doctrine, leaving the respondent (and the reader) to recover for themselves the philosophical considerations underlying it. They thus emphasized the conceptions of virtue as knowledge, of virtue as unified in wisdom, and of voluntary action as motivated always by an agent's beliefs about what is best to do, that emerged through Socrates' examination of Protagoras (see §§6-7). They thought these constituted a positive, Socratic moral philosophy, and in their own moral theory they set out to revive and strengthen it with systematic arguments and with added metaphysical and physical speculations of their own. Later Stoics regularly referred to Socrates as a genuine wise man or 'sage', perhaps the only one who ever lived. He had brought to final, systematic perfection his knowledge, along Stoic lines, of what is good and bad for human beings, and what is not, and therefore possessed all the virtues and no vices, and lived unwaveringly the best, happy life, free from emotion and all other errors about human life. It is a tribute to the complexity and enigmatic character of Socrates that he could stand simultaneously as a paragon both of sceptical, non-committal inquiry and life led on that uncommitted basis, and of dogmatic knowledge of the final truth about all things human.

The figure of Socrates has continued to fascinate and to inspire ever-new interpretations of his innermost meaning. For Montaigne, he proved that human beings can convincingly and attractively order their own lives from their own resources of mind, without direction from God or religion or tradition. In the nineteenth century Kierkegaard and Nietzsche offered extensive interpretations of him, both heavily dependent upon Hegel's absolute-idealist analysis. Hegel interpreted Socrates as a quintessentially negative thinker, aiming at making people vacillate in their superficial moral beliefs and endorse none of them wholeheartedly, thus hinting that the truth, although universal and objective, lies deep within the freedom of their own subjectivity. For Kierkegaard he represents, on

the contrary, the possibility of living wholeheartedly by occupying an unarticulated position somehow beyond the negative rejection but expressed through it: ‘infinite absolute negativity’. In *Die Geburt der Tragödie (The Birth of Tragedy)* Nietzsche treats Socrates principally as having poisoned the ‘tragic’ attitude that made possible the great achievements of classical culture, by insisting that life should be grounded in rational understanding and justified by ‘knowledge’; but his fascinated regard for Socrates led him to return to him repeatedly in his writings. Socrates was paradigmatically a philosopher whose thought, however taken up with logic and abstract argument, is inseparable from the search for self-understanding and from a deeply felt attachment to the concerns of human life. His power to fascinate and inspire is surely not exhausted.

Socratic dialogues

After Socrates' death in 399 BC, a number of his followers composed imaginary dialogues between Socrates and various persons, usually historical. In addition to the dialogues of Plato there were works by Antisthenes, Aeschines, Phaedo, Euclides and, somewhat later, Xenophon. Only the writings of Plato and Xenophon have survived intact. The portrayal of Socrates varied from author to author, but the charismatic personality and skilful questioner is recognizable in each version. The connection between love and Socratic philosophy was frequently illustrated in Socrates' relationship to Alcibiades. The erotic theme was also represented in the role played by Aspasia, Pericles' mistress, in at least four authors, including Plato. Historical fact and even chronological possibility were regularly disregarded. This was essentially a genre of fiction.

1 The dialogue as a fictional genre

Socratic dialogues or 'Conversations with Socrates' (*Sōkratikoi logoi*) are recognized as a literary genre by Aristotle (*Poetics* 1), who is reported to have named a certain Alexamenos of Teos as the first author of such works. We know nothing further of Alexamenos, but we have remains from dialogues by Antisthenes, Aeschines, Phaedo and Euclides, in addition to the extant works of Plato and Xenophon. There must have been others, but the titles listed by the biographer Diogenes Laertius (II 12-16), of works by Crito, Simon the shoemaker, Glaucon, Simmias and Cebes, are probably all spurious.

The conversations are fictitious. Socrates' interlocutors are typically historical, but even here there are exceptions. The unwashed Pythagorean Telauges, after whom one of Aeschines' dialogues is named, is likely to be an imaginary stereotype. And in Plato, Ion as typical rhapsode and Callicles as the unscrupulous politician, ideologically 'liberated' by the Enlightenment, may well be fictitious characters. The contrast with history is clearest in the case of Xenophon, who wrote historical works as well as Socratic dialogues. When Xenophon in the *Memorabilia* or the *Oeconomicus* says 'I was there when Socrates said…,' no one is expected to believe him. He begins his *Symposium* with the remark that he was present at the occasion. But the fictive date is set in 421 BC, when Xenophon would have been a child, and Xenophon is in fact not mentioned again in the dialogue. His claim to have been present seems to be only a device for introducing the narrative form without specifying a narrator.

In Aeschines' *Aspasia*, the occasion itself is fantastic. When asked by Callias to recommend a moral tutor for his son, Socrates proposes Aspasia, Pericles' mistress and a symbol of loose living in Attic comedy. The episodes are all chronologically dubious. Thus Aspasia is represented as interrogating Xenophon and his wife, although Aspasia must have been long dead before Xenophon was old enough to get married. In Aeschines' *Alcibiades* we find Alcibiades bursting into tears and laying his head on Socrates' knees, which is no more likely to be historical than the bedroom scene reported by Alcibiades in Plato's *Symposium*. In Phaedo's dialogue *Zopyrus*, an oriental sage of that name arrives in Athens and offers to read Socrates' character from his appearance. The diagnosis is surprising: Socrates is described as a sensualist. Both the episode and Zopyrus himself seem to have been invented by Phaedo in order to permit Socrates to respond: 'Such are my native tendencies, but they have been overcome by philosophy.'

Plato is probably unique in creating the illusion of historical reality for his dialogues (although Xenophon has tried to imitate this in his own *Symposium*). Historians have been misled therefore into dating Parmenides and Zeno by their trip to Athens, imagined by Plato in the *Parmenides*. Here again it seems clear that the occasion was invented for dramatic and philosophical reasons, since in Plato's eyes only Parmenides deserved the honour of refuting Socrates and criticizing the doctrine of Forms. The fictional character of the genre is even more obvious in Plato's *Menexenus*. There Socrates delivers a funeral oration which alludes to events of 386 BC (thirteen years after his own death), but the speech is attributed to Aspasia, who made it 'from the scraps left over from the funeral oration she composed for Pericles in 431 BC (*Menexenus* 236b).

2 Literary interaction and common themes

By introducing Aspasia as author of funeral orations, Plato is developing a motif from Aeschines' *Aspasia*, where Aspasia is said to have taught rhetoric to Pericles and sharpened his tongue on the whetstone of Gorgias (fr. 22 Dittmar, A65 Giannantoni). We can trace this literary contact between Aeschines and Plato in several dialogues,

and in both directions. Literary interaction on a larger scale is found in the erotic themes that are common to all the known Socratic authors. Thus dialogues named *Alcibiades* and *Aspasia* were composed both by Antisthenes and by Aeschines. Euclides is also credited with an *Alcibiades*, and with an *Eroticus* as well (unless these are two names for the same work). And, as we have seen, Phaedo's *Zopyrus* dealt explicitly with Socrates' erotic temperament. As generally with Socrates, we cannot know just what historical reality underlies this well-defined Socratic literary theme. What we can see is that Plato's treatment of love (*erōs*) in the *Lysis* and *Symposium*, and the erotic allusions to Alcibiades in the *Gorgias* and *Protagoras*, are firmly rooted in the Socratic literary tradition. Diotima in the *Symposium* seems to be Plato's answer to Aeschines' Aspasia, who gives a Socratic lesson on virtue to Xenophon and his wife.

There are many examples of Platonic influence on Xenophon, who seems also to have absorbed material from Antisthenes and Aeschines. There is no trace of Xenophon's Socratic writings in Plato.

3 The historical Socrates?

Parallels between different Socratic authors may allow us to catch a glimpse of the historical Socrates. Thus there is an interesting parallel to the Platonic Socrates' avowal of ignorance in Aeschines' *Alcibiades*, where Socrates insists that it was not by any art (*technē*) or knowledge (*mathēma*) that he thought he could help Alcibiades in his quest for virtue, but only by love (fr. 11 Dittmar, A53 Giannantoni). The same dialogue depicts an elenchus, in which Socrates succeeds in bringing Alcibiades to a consciousness of his own ignorance and need for improvement - not by a systematic argument, however, but by presenting him with the model of Themistocles, in comparison to which Alcibiades feels immensely inferior. This confirms the suggestion given in several Platonic passages (for example, *Apology* 24-7 and *Laches* 187e-188b), that the original elenchus was more a testing of persons than of propositions.

4 External form

The earliest Socratic dialogues are likely to have been in simple mime form (without narration or dramatic proem) as in Plato's *Crito*, *Ion*, and *Hippias Minor*. Aeschines' *Alcibiades* is more complex: it is narrated by Socrates and located in a gymnasium, like Plato's *Charmides* and *Lysis*. Antisthenes may have introduced himself into the dialogue as narrator or interlocutor, as Xenophon does (and later Cicero); whereas Plato and (as far as we know) Aeschines never appear in their own works. From the literary point of view, Aeschines was probably the most gifted Socratic author after Plato. But this was originally a minor genre, comprising short works like the *Ion* and *Hippias Minor*. With large compositions like the *Gorgias* and *Protagoras* Plato transformed the Socratic dialogue into a major art form, the vehicle for his own philosophy.

Writing after Plato, Xenophon composed the *Memorabilia* as a large work by putting together many mini-dialogues. In form, Xenophon's *Symposium* is loosely modelled after Plato's work of that name, although the content is altogether different.

Socratic schools

*For approximately one and a half centuries after Socrates' death in 399 BC, several Greek philosophical schools and sects each claimed to be the true intellectual heirs of Socrates. Later doxographers emphasized the Socratic pedigree of each of these schools by establishing an uninterrupted succession (*diadochē*) between its alleged founder, who was invariably a member of Socrates' own entourage, and the philosophers who succeeded him as leaders of the school.*

*Leaving aside Plato, the founder of the Academy, the members of the Socratic circle who left a succession behind them are Antisthenes, Aristippus of Cyrene, Euclides of Megara, and Phaedo of Elis, considered respectively the founders of Cynicism, and of the Cyrenaic, Megarian and Elian schools. It is these groupings, plus several of their offshoots, that are conventionally known as the '*Socratic schools*'. All can be seen as, in their own ways, developing Socrates' ethical outlook, and several were concerned with exploring the logical and metaphysical implications of his dialectical principles.*

1 Cynics, Cyrenaics, Megarians and Dialecticians

The Cynic movement appears intermittently for a period of about ten centuries, from the fourth century BC to the sixth century AD. Its archetypal figure was Diogenes of Sinope, whose bohemian lifestyle and beggarly appearance exemplified the unity of principle and practice governing early Cynicism. Although Antisthenes (§1) was looked back on as the founder of Cynicism, his connection with the movement is problematic. Lacking any institutional structure, it could not, in any formal sense, have a founder. Nor can he be considered the forerunner of the kind of philosophical instruction practised by the Cynics, since unlike Antisthenes they undermined curricular education, preferred practical example to philosophical argumentation and adopted informal means of instruction (see Cynics §1).

However, there is a sense in which the claims that Antisthenes is the predecessor of the movement and that the Cynics as a Socratic school are legitimate. Antisthenes is often considered the closest associate of Socrates, as reflected in both his logic and his ethical doctrine. In ethics, he shared the intellectualism of the Platonic Socrates, in that he considered virtue an understanding which, once acquired, amounts to wisdom and cannot be lost. But he also stressed the importance of physical and mental exercise, and the strength of character by which one overcomes one's weaknesses and achieves virtue. This moderated version of Socratic intellectualism provides a substantial common ground between the doctrine of Antisthenes and those of various Cynics.

The Cyrenaic school clearly counted as Socratic because founded by an associate of Socrates, Aristippus of Cyrene, whose own descendants succeeded him as the leaders of the school. Philosophically however, its doctrines have often been considered un-Socratic. For in ethics the Cyrenaics held various versions of hedonism, and several of them maintained that the bodily pleasure experienced at the present moment is the moral end. Again, in epistemology they developed a radical scepticism regarding our knowledge of the properties of external objects, whereas much of the evidence for Socrates suggests that, at least in the period in which Aristippus would have known him, he was concerned primarily with ethics. None the less, there were ways in which the Cyrenaics could reasonably claim that they remained faithful to the spirit of Socratic philosophy (see Cyrenaics §5; Aristippus the Elder).

The Socratic pedigree of the Megarian school is secured through Socrates' friend Euclides, who founded the school in his native Megara, although it is widely held to have been influenced also by the Eleatic philosopher Parmenides. Its doctrines were ethical and metaphysical, and also concerned philosophical methodology and logic. Euclides taught an ethical monism related to the doctrine of the unity of virtue held by the Platonic Socrates and, perhaps, to the belief of Xenophon's Socrates in a providential universe that, presumably, is wholly good (see Megarian school).

The Megarians overlapped for about fifty years with the rival school of the Dialecticians, linked with Socrates via its founder, Clinomachus of Thurii, himself a pupil of Euclides. Although this school's speciality was apparently the development of dialectical skills for their own sake, it was classified as one of the ten ethical sects which developed the ethical part of philosophy that originated with Socrates (see Dialectical school).

2 The Elian and Eretrian schools

The Elian school was founded by Socrates' associate, Phaedo of Elis, soon after Socrates' death. Its founder is recorded as the author of several Socratic dialogues, of which only the *Zopyrus* and *Simon* were certainly his own works (see Socratic Dialogues §1). The evidence suggests that both dialogues explored ethical subjects. The *Zopyrus*, named after a fifth-century physiognomist, probably aimed to modify the principle that there is an intrinsic relation between natural disposition and bodily form by arguing that the first can be entirely transformed - as in Socrates' own life - by the power of philosophy. *Simon* may have discussed various conceptions of virtue and its relation to pleasure, and perhaps defended a position according to which certain joys or pleasures are compatible with virtue. The themes linking the two works and securing a Socratic pedigree for Phaedo are the healing and reformative power of philosophy, its appropriateness for every person in every condition, the gradual and imperceptible effects of good and evil habits, and the importance of spiritual freedom with regard to external circumstances.

Phaedo's immediate successor was Plestanus of Elis, otherwise unknown. Anchipylus and Moschus, also from Elis, are listed as members of the Elian school, although Cynic features are attributed to them as well. But the most important philosophical heir of Phaedo was Menedemus of Eretria, after whom the school was relabelled the 'Eretrian school'. His criticisms of Plato, of Xenocrates, of the Cyrenaic Paraebates, of the Megarian Alexinus and of Aeschines suggest that he too was bidding for the mantle of Socrates. Even the testimony that he wrote nothing and did not adhere firmly to any doctrine may point to deliberate imitation of Socrates. However, a number of logical, metaphysical and ethical tenets are attributed to him. Reportedly, he accepted affirmative propositions and simple propositions but disallowed negative, complex or conditional statements. Although the point of this position is unclear, it may have been related to his beliefs that each thing can only be called by its own name, and that nothing must be at once one and many. These led him to remove the verb 'to be' from sentences such as 'that man is pale' and to remodel them with a periphrasis involving no use of the copula. In these respects, as well as in the commendation of tautologies, Menedemus' doctrine approaches Antisthenes' logic (see Antisthenes §4). Although he argued with great keenness and occasionally used paradoxes, he rejected Megarian eristics; on this account too Menedemus could claim to be faithful to the spirit of Socrates.

In ethics, Menedemus maintained that virtue is one thing called by many names, and probably implied that names which conventionally designate the different virtues are in fact synonyms - a point on which the Platonic Socrates is notoriously ambiguous. He espoused Euclides' position concerning the unity of the good (see §1) and he probably identified the good with virtue. He shared the intellectualism of other Socratics in that he placed the supreme moral good in the soul and believed that it can be achieved only by means of philosophical education which, therefore, is the single most important activity. But his bodily habits indicate that, like Antisthenes and the Cynics (see §1), he attributed moral importance to physical training as well. His proneness to superstition may suggest that he believed in a providential universe and, perhaps, in a divine creator. If so, his beliefs are comparable to those of Xenophon's Socrates and of Euclides. He took an active part in politics (a fact much resented by the Cynics), but similarly to many Socratics he kept his dignity, frankness and spiritual independence in the face of the powerful men of his day. His end, sadly, is reminiscent of Socrates' own: he was unjustly denounced for treason but, unlike Socrates, he left Eretria and died in exile by his own hand.

3 How Socratic are the Socratic schools?

Apart from the fact that the Socratic schools are founded by the entourage of Socrates, one should perhaps not attempt to find one single common thread unifying them. The links between them consist rather in family resemblances, between Socratics of the same generation or of different generations, many of them attributable with greater or lesser plausibility to Socrates himself. For example: Antisthenes and Aristippus stressed the importance of self-mastery and self-control regarding pleasure; Antisthenes and Phaedo considered some pleasures entirely compatible with virtue; Aristippus and the Cynics adopted the political attitudes of cosmopolitanism and of detachment from obligations to any particular city; Menedemus veered towards the ethics of the Cynics, and also held similar positions to Antisthenes in logic; the Megarians and the Dialecticians also worked on similar logical topics, such as modality, although their inquiries differed in scope and depth; Antisthenes, Stilpo, Menedemus and, perhaps the Dialecticians, subscribed to various forms of the doctrine that each thing has only one essence and that there is only one *logos* describing it (see Logos §1).

Some of the schools appear more formally organized than others. Aristippus and Phaedo probably ran proper schools, Antisthenes had a steady number of followers identified as ‘the Antisthenians’; the Cynics and the later Cyrenaic sects were dispersed; and Menedemus was entirely informal in his teaching. Nevertheless, the label ‘Socratic’ is to a certain extent justified. The doctrinal links both with each other and with the views attributed to the historical Socrates are symptomatic of the competition, widespread in the fourth century BC and after, to recover and expound Socrates’ authentic teachings.

Solidarity

Solidarity exists among a group of people when they are committed to abiding by the outcome of some process of collective decision-making, or to promoting the wellbeing of other members of the group, perhaps at significant cost to themselves. Many regard solidarity as an important political ideal on the grounds that it is related to community and fraternity, and conducive to social cohesion and stability. Some individualists, however, believe that it is incompatible with autonomy on the grounds that full autonomy requires one always to take the final decision oneself about what one should do.

Solidarity is generally seen in two ways. First, as a commitment to other members of a group to abide by the outcome of their collective decision-making. Second, as a concern for other members of a group, which may require an unwillingness to receive a benefit unless the others do, or an unwillingness to receive a benefit when this will harm them. This commitment to the wellbeing of others is sometimes conceived in terms of the recognition of special obligations between the members of a group, which exist in virtue of their being members of it.

Solidarity has been of interest to social theorists concerned with the issue of what bonds unite people together in societies (see, for example, Durkheim 1983) (see Durkheim, É. §3). An understanding of the causes of solidarity can provide an insight into what makes societies stable, and what leads them to disintegrate. Because of its potential contribution to social stability and cohesiveness, solidarity has been regarded as instrumentally valuable.

Many political philosophers, particularly communitarians, have supposed that solidarity is also intrinsically valuable, believing that there is a conceptual connection between it and community or fraternity (see Community and communitarianism). For some communitarians, part of what it is to be a member of a community is to be in a reciprocal relationship of solidarity with the other members.

Socialist theorists have had special reasons for valuing solidarity because they have regarded it as a weapon against exploitation by capitalists, both in the struggle for better wages and conditions within the capitalist system, and in the fight against that system (see Socialism). Reformist socialists have thought that strikes are likely to be effective only if there is solidarity among the workers. Some revolutionary socialists have thought that capitalism will be overthrown only if there is solidarity among the working class in general.

The existence of solidarity can provide a way of out situations which have the structure of a ‘prisoner’s dilemma’ (see Rational choice theory §2). In the original prisoner’s dilemma, two prisoners who have committed a certain crime are interviewed separately and offered a deal. If only one confesses, that prisoner alone will be released, whereas the other will receive a harsh sentence. If both confess, each will receive an intermediate sentence. If both refuse to confess, they will get a milder sentence for some different crime which can be proved independently of either confessing. If each prisoner is concerned solely with their own interest, it is rational for them to confess, even though if neither confesses the outcome will be better for each. But if each is unwilling to receive a benefit when this will harm the other, then each will refuse to confess, and both will be better off.

Solidarity will not, however, provide a way out of every such situation, because in many-person cases, it is often the case that one’s own actions, even when motivated by a consideration of the good of others, will make no appreciable difference to the overall outcome. Consider, for example, the question of whether I should modify my car to reduce emissions from it. In such cases, it is not clear that solidarity will or should make any difference to my reasoning, except in the special case in which my community can be understood to have made some collective decision, perhaps to reduce emissions from cars, and solidarity is understood as a commitment to abide by such decisions. This kind of problem apparently besets Marxist analyses of how the revolution against capitalism will occur. One person’s contribution will make no difference to whether the revolution will occur, so what reason does any individual have to expend energy in attempting to bring it about, even if they have a sense of solidarity with other working-class people?

Not everyone values solidarity, however, and even those who do value it may disagree about when it is valuable. It might be argued that solidarity is valuable only when channelled in pursuit of morally permissible or worthwhile goals. More fundamentally, someone might doubt whether solidarity is ever valuable because they believe that it is

incompatible with personal autonomy (see Autonomy, ethical). R.P. Wolff (1970), for example, argues that being autonomous always involves taking the final decision about what one should do, and that it is incompatible with any form of commitment requiring that one should act in accordance with the outcome of collective decision-making. First, however, not all conceptions of autonomy require that one should always retain the final decision about how to act. Second, even if autonomy is valuable and is incompatible with solidarity, this does not show that solidarity has no value, for perhaps there can be genuine values that are incompatible with one another (see Moral pluralism). Third, a commitment to act in accordance with the outcome of a process of collective decision-making need not mean that one accepts that outcome uncritically. One might, for example, simply give the fact that it is such an outcome considerable weight in making the final decision about what one should do.

There are also disputes about the sort of relationships in which solidarity can be realized. Some maintain that solidarity is feasible only for small groups, whereas others believe that it is realizable among large groups. A society in which everyone willingly accepted and acted from what John Rawls (1971) has termed ‘the difference principle’ might be thought to embody solidarity (see Rawls, J. §§1-2). The difference principle holds that inequalities in a society are permissible only if they benefit (or at least, do not harm) the worst-off. If the best-off were willing to forego benefits when by accepting them they would harm the worst-off, then solidarity would exist between them. Richard Rorty (1989) has argued that it makes sense to aim at solidarity even at the global level (see Rorty, R. §3). In his view solidarity would require not a belief in a shared human essence, but rather an ability to see traditional differences (for instance, those between tribes, nations, religions and races) as unimportant compared to our shared capacity to experience pain and humiliation.

Solipsism

'Solipsism' (from the Latin solus ipse *- oneself alone) is the doctrine that only oneself exists. This formulation covers two doctrines, each of which has been called solipsism, namely (1) that one is the only self, the only centre of consciousness, and, more radically, (2) that nothing at all exists apart from one's own mind and mental states. These are not always distinguished from corresponding epistemic forms: for all we know, (1) or (2) might be true.*

A more recent coinage is 'methodological solipsism', which has a quite different meaning: that the content of an individual's thoughts is fully determined by facts about them, and is independent of facts about their environment.

Philosophical interest in solipsism does not arise from the fact that some significant philosopher has advocated it, for none has done so. Rather, solipsism has played dialectical roles, as for instance when philosophers try to argue that their opponents' positions, consistently pursued, lead to solipsism - and are thereby shown to be harbouring an absurdity. It plays another such role when philosophers ask whether there are any rational considerations capable of refuting it. More extreme forms of scepticism are sometimes treated in the same way - unsurprisingly, since the epistemic versions of solipsism are themselves extreme forms of scepticism.

That one is, for all one knows, the only centre of consciousness, is precisely the traditional problem of other minds (see Other minds). It can be based on the thoughts that one has no direct awareness of the mental states of others, and that to infer that they must have mental states because of the outward resemblance between their bodily behaviour and one's own is to make an inference based on one case only - not normally regarded as sound inductive procedure. Another, more radical, argument is that one is unable even to form any concept of a state of consciousness that is not one's own. This approach is discussed by Wittgenstein - who was not, however, recommending that we should accept its conclusion, but rather that we should abandon the natural, though mistaken, conception of a state of consciousness which leads us into it. On a right understanding of the matter, ascriptions of mental states to ourselves and to others are co-ordinate achievements. Solipsists wrongly think they can ascribe such states to themselves and *then* consider the question whether other human bodies have associated mental states as well (see Criteria; Private language argument).

The second type of solipsism, which finds problematic not just the existence of other minds but of *everything* other than one's own mind and mental states, is a very close relation of scepticism about the existence of the external world (see Scepticism). Although closely related, it is not the same thing, since a number of philosophers from widely varying traditions have denied the existence - or at least the independent existence - of a material world, while showing no tendency to assert that theirs was the only mind. Berkeley is a prime example, and Dharmakīrti, having portrayed the material world as illusory, wrote a treatise explaining why solipsism was not an inevitable consequence.

The expression 'methodological solipsism' is a recent coinage popularized by, in particular, Hilary Putnam and Jerry Fodor. This phrase refers to the view that the content of an individual's thoughts is fully determined by intrinsic, non-relational facts about that individual, hence is not affected by the nature of the objects that form their environment (see Content: wide and narrow; Methodological individualism).

Soloveitchik, Joseph B. (1903-93)

Joseph B. Soloveitchik was a Jewish philosopher in the fullest sense. For such thinkers, the task of building intellectual and spiritual bridges between their particular traditions and other cultures permeates and shapes all their philosophic commitments and endeavours.

Medieval philosophers sought to integrate the competing knowledge claims of natural reason and authoritative revelation. Soloveitchik, by contrast, ignored metaphysics and epistemology, focusing instead on refuting the alleged incompatibility between Judaism and the active, human-centred ethos of modernity. His major concern was not the truth of religion but the relevance and significance of religious human types and ideals in modern Western culture.

1 *Halakhic* man as religious hero

Unlike Buber, who introduced traditional Judaism to modern Western culture by focusing on such universal themes as religious existentialism, pietism and mysticism, Soloveitchik introduced a new human archetype into the philosophic discussion: the *talmid hakham*, the Talmudic scholar, the hero of the eastern European (especially Lithuanian) Jewish intellectual tradition. Although such a figure seems *prima facie* to be the very obverse of the modern, triumphant man of action, Soloveitchik set out to reveal the implicit modern human spirit of the Talmudic scholar. The culture of Talmudic learning, Soloveitchik showed, was unique in its conceptual methodology and distinctive in its consuming devotion to study. Its values of intellectual rigour, integrity, boldness and creativity cultivated a human type that personified a special variety of human independence, autonomy and self-worth - the principal characteristics of the hero of modern Western culture.

Soloveitchik’s methodology, which he pursues in later writings, consists in constructing contrasting human types, in this case cognitive man versus *homo religiosus*. The former is an archetype of the modern scientist - this-worldly, action-oriented, confident, triumphant, at home in the world. *Homo religiosus*, on the other hand, is guilt-driven and grace-oriented, a spiritual manic-depressive who oscillates between a disgust for this imperfect world and a longing for the transcendent perfection of the divine reality.

Unlike his countertype, the man of natural religion, who is torn between self-negation and self-glorification, *halakhic* man possesses an objective normative way of life which fortifies him against the wild fluctuations of subjectivity, giving him a permanent sense of legitimacy and self-worth. The performance of *mitzvot* (commandments) entails a sense of covenantal responsibility which confirms the doer, as God’s, that is, the covenantal partner - with dignity and legitimacy.

In Soloveitchik’s conceptual scheme, not only law and the Sinaitic covenant but also the biblical narrative of creation itself constitutes a mandate enjoining human autonomy and dignity. Soloveitchik makes a bold exegetical move by extending the idea of *imitatio Dei* (which is applied to ethical attributes in rabbinic literature to include the attribute of God as creator). Creative human behaviour becomes metaphysically similar to divine creativity.

Spinoza had claimed that the Judaic legal tradition fostered a slave morality that inhibited the development of personal moral responsibility. Soloveitchik countered both this and Kant’s critique of Judaism for holding to what he deemed a heteronomous ethics by arguing that *halakhic* man appropriates the heteronomous, revealed norm as an autonomous, self-created norm (see Kant, I.). Soloveitchik himself creatively showed how modern existentialist typologies could find roots in *halakhah*.

2 ‘The Lonely Man of Faith’

In later works, Soloveitchik’s protagonist changes from the heroic *halakhic* man (in many ways a counterpart to the archetypal ideal of American Pragmatism) into a more dialectical, existentialist figure: the lonely man of faith. The empathy of Soloveitchik’s prose shift from the active, outward-directed virtues of creativity and autonomy, to the more introspective, radically personal experiences of loneliness, crisis and defeat.

The essay ‘The Lonely Man of Faith’ (1965) discusses two human types derived from the two creation stories in Genesis: ‘Adam the first’ is created in the image of God, together with Eve, and ordered by God to ‘fill the earth and master it’ (Genesis 1: 28); ‘Adam the second’ is fashioned alone from the dust of the earth by God, who

responds to his existential predicament ('It is not good for man to be alone' (Genesis 2: 18)) by creating another human being.

While this typological structure resembles the dichotomy between the cognitive-man and *homo-religiosus* of *Ish ha-Halakhah (Halakhic Man)* (1944), the superior human synthesis, now called covenantal man, is less weighted in favour of assertiveness and adequacy. Here we find the strong countervailing influence of existential loneliness and defeat.

Adam the first fulfils the mandate of the impersonal God of Being by pursuing science and technology and by gaining dominion over an impersonal nature. Adam the second responds to an inner, existential need by seeking relationship with another individual or indeed, with a personal God (Adonai, the Lord, the God who is named by the Tetragrammaton).

Soloveitchik argues that *halakhic* culture addressed the second Adam's existential quest through the covenant and the *mitzvot*. The individual can transcend temporality and personal death through participation in the normative history of the Jewish people. The existential need for relationship can be met by encountering a God who addresses one as thou and with whom one can share in a relationship of covenantal mutuality. The fundamental point of the covenantal faith community of Adam the second is that it seeks redemption through sacrifice, even in defeat and retreat. The underlying crisis calling for redemption is loneliness rather than sin or inadequacy.

The man of faith is far more complex than his heroic predecessor, *halakhic* man. Like the latter, he knows that achieving and expressing individual dignity and adequacy are integral constituents of the total faith gesture. Human majesty and creativity are forms of *imitatio Dei*. Faith thus requires that the man of faith be creative, free and assertive, as well as obedient, subservient and sacrificial. The God who commands the former also commands the latter (see Faith).

Solov'ëv, Vladimir Sergeevich (1853-1900)

It has been widely acknowledged that Vladimir Solov'ëv is the greatest Russian philosopher of the nineteenth century; his significance for Russian philosophy is often compared to the significance of Aleksandr Pushkin for Russian poetry. His first works marked the beginning of the revolt against positivism in Russian thought, followed by a revival of metaphysical idealism and culminating in the so-called Religious-Philosophical Renaissance of the early twentieth century.

Unlike the Russian idealists of the Romantic epoch, Solov'ëv was a professional, systematic philosopher. He created the first all-round philosophical system in Russia and thus inaugurated the transition to the construction of systems in Russian philosophical thought. At the same time he remained faithful to the Russian intellectual tradition of reluctance to engage in purely theoretical problems; his ideal of 'integrality' postulated that theoretical philosophy be organically linked to religion and social practice. He saw himself not as an academic philosopher, but rather as a prophet, discovering the way to universal regeneration.

One of the main themes of Solov'ëv's philosophy of history was Russia's mission in universal history. Owing to this he was interested in the ideas of the Slavophiles and, in the first period of his intellectual evolution, established close relations with the Slavophile and Pan-Slavic circle of Ivan Aksakov. He was close also to Dostoevskii, on whom he made a very deep impression. At the beginning of the 1880s he began to dissociate himself from the epigones of Slavophilism; his final break with them came in 1883, when he became a contributor to the liberal and Westernizing Vestnik Evropy (European Messenger). The main reason for this was the pro-Catholic tendency of his thought, which led him to believe that Russia had to acknowledge the primacy of the Pope. In his view, this was a necessary condition of fulfilling Russia's universal mission, defined as the unification of the Christian Churches and the establishment of a theocratic Kingdom of God on earth.

In the early 1890s Solov'ëv abandoned this utopian vision and concentrated on working out an autonomous ethic and a liberal philosophy of law. This reflected his optimistic faith in liberal progress and his confidence that even the secularization of ethics was essentially a part of the divine-human process of salvation. In the last year of his life, however, historiosophical optimism gave way to a pessimistic apocalypticism, as expressed in his philosophical dialogue Tri razgovora (Three Conversations) (1900), and especially the 'Tale of the Antichrist' appended to it.

1 The philosophy of All-Unity

Vladimir Solov'ëv was the son of Sergei Solov'ëv, a leading Westernizing historian and professor at Moscow University. After the brilliant defence of his master's thesis, *Krizis zapadnoi filosofii: protiv pozitivistov (The Crisis of Western Philosophy: Against the Positivists)* (1874), he began lecturing at St Petersburg University. His academic career, however, proved to be short-lived. The assassination of Alexander II (March 1881) prompted him to give a public lecture in which, while condemning the revolutionary terrorists, he appealed to the new tsar to spare their lives. As a result he was forbidden to lecture in public and shortly afterwards resigned from the university.

The general outline of Solov'ëv's philosophy follows the Neoplatonic scheme of self-enriching alienation. Conceiving the world as the divine absolute in the process of becoming, he distinguished in it three moments, corresponding to the three persons of the Holy Trinity: the moment of a static, undifferentiated unity, the moment of individuation and differentiation and, finally, the highest moment of a free, differentiated unity. In his *Filosofskie nachala tselnogo znaniya (Philosophical Principles of Integral Knowledge)* (1877) and in his doctoral dissertation, *Kritika otvlechënnych nachal (The Critique of Abstract Principles)* (1880), Solov'ëv applied this scheme to human history and knowledge. In the evolution of humankind, he argued, the first phase (substantial monism) was represented by the Eastern world (including nineteenth-century Islam), and the second phase (atomism) by Western European civilization. During the first phase the three spheres of human activity - creativity, knowledge and social practice - were entirely subordinated to religion. In the sphere of creativity, technology (the material grade) was fused with art (the formal grade) and mysticism (the highest, absolute grade) in a mystical *theurgy*. In the sphere of knowledge, positive science (the material grade) was fused with abstract philosophy (the formal grade) in an undifferentiated *theosophy*. In the sphere of social practice, the economic self-government or

zemstvo (the material grade) was fused with the state (the formal grade) and the Church (the absolute grade) in a homogeneous *theocracy*. In the second evolutionary phase the different grades within each sphere strove for absolute autonomy and mastery over one another. In the resulting struggle matter conquered spirit: the final outcome of Western civilization was materialistic socialism (the true scion of capitalism) in the social sphere, positivism in the sphere of knowledge, and utilitarian realism in the sphere of creativity. Now the time had come for the third phase - that of *free unity* - in which the separate spheres and grades of human creativity, knowledge and social practice would once more be united, but without losing their distinctiveness: as a free theurgy, a free theosophy and a free theocracy. The mission of inaugurating this universal regeneration and reintegration of human life was to be fulfilled by the Russians.

In the sphere of knowledge Solov’ëv distinguished three types of philosophy - naturalism (empiricism), rationalism and mysticism. Empiricism and rationalism took different paths to arrive at the same result - the denial of the substantial reality of both the external world and the knower himself. Following the elderly Schelling and the Slavophiles, Solov’ëv saw Hegelianism as the last word in rationalism (see Schelling, F.W.J.; Slavophilism). He accused Hegel of creating a merely ’negative’ philosophy, dealing only with empty concepts, and, like Schelling, set against this a programmatically ’positive’ philosophy, rehabilitating ’the given’. It involved a rehabilitation of nature, as a manifestation of the divine absolute, and, above all, a philosophical interpretation of the Christian revelation.

The central idea in Solov’ëv’s system was that of positive ’All-Unity’. He also used Kireevskii’s concept of ’integral wholeness’ (see Slavophilism §1) but interpreted it differently, stressing that free unity presupposes the differentiation of the original wholeness and autonomization of different spheres of life and knowledge. Therefore, Western civilization, including Western philosophy, was for him not a ‘wrong path’ (as it was for the Slavophiles), but a necessary phase of human development.

2 Godmanhood and Sophia

Solov’ëv’s reinterpretation of Christianity revolves around the concept of Godmanhood, developed by him in a series of extremely successful lectures in St Petersburg *Chteniia o bogochelovechestve (Lectures on Godmanhood)* (1877-81). The concept of ’God made man’, Solov’ëv asserted, does not assume either a dualistic belief in the transcendence of God, or a pantheistic belief in his immanence in the world. God is both immanent and transcendent, and the mediating principle that allows the world to become transfused by the divine spirit is Man. The ultimate purpose of the universe is to achieve the stage of a free, innerly differentiated All-Unity. The cosmic history began with a dramatic event: the soul of the world, or Sophia, had once fallen away from the divine Logos, plunging the world into a chaotic struggle of hostile elements. The second act of the cosmic drama was the appearance of man. Since then Sophia, having identified itself with ’ideal humanity’, began to ascend to a renewed unity with God in Godmanhood. The union of Logos with Sophia, of God with man, was accomplished in Jesus Christ. The incarnation of God in Jesus was thus the central event in the entire cosmic process. Even this, however, was only the beginning of the soteriological process. To finish the work of salvation, that is, to achieve the universal regeneration and transfiguration of the world, it was necessary to pass through all stages of human history and to realize the destiny of man in the Kingdom of God on earth.

The concept of Sophia in Solov’ëv’s philosophy is somewhat ambiguous and subject to different interpretations. In some of his writings Solov’ëv defined Sophia, or the Wisdom of God, as ’the substance of the Holy Ghost’, the passive, female element in God, ‘external Womanhood’. In the autobiographical poem ’Three Meetings’ he identified Sophia with the mysterious feminine being which visited him in his mystic visions. He was thoroughly acquainted with a vast mystical and theosophical literature on Sophia: in the Bible (Solomon’s Proverbs), in the Kabbalah (where Sophia is presented as a woman) (see Kabbalah), in the writings of the gnostics (where it is ‘divine matter’ and the ’feminine aeon’) (see Gnosticism §4), in Jakob Boehme (who identified it with ’eternal virginity’), in Emanuel Swedenborg and Louis-Claude Saint-Martin. He thought that the idea of Sophia was particularly close to the traditions of Eastern Christianity, and saw a proof of this in an old icon with the image of Sophia in the cathedral of Novgorod. In the most general terms it may be said that he needed the concept of Sophia to define divinity within the world, unity in the creation, and the link between the world and the transcendent God.

As ’the feminine principle in God’ Sophia was bound up with Solov’ëv’s theory of sexual love, expounded in *Smysl liubvi (The Meaning of Love)* (1892-4). It claimed that the real significance of love consists not in

procreation, which is merely the absurd multiplication of mortal beings, but in the human striving for the likeness of God in a restored androgynous unity.

Solov’ëv’s vision of universal reintegration can also be found in his aesthetics. As a motto for his essay ‘Beauty in Nature’ (1889) Solov’ëv chose Dostoevskii’s words ’Beauty will save the world’. Natural beauty, he maintained, is a manifestation of the concrete operations of the Absolute in the material world; by ’transilluminating’ and spiritualizing matter, beauty helps to raise the fallen World Soul and to introduce an element of the divine into reality. In the essay ’The Overall Meaning of Art’ (1890) Solov’ëv applied this conception to artistic beauty: art, he argued, is an instrument of reintegration, a theurgic force capable of ’transilluminating’ and transforming the human world.

3 Theocratic utopia

Russia’s mission in universal history was defined by Solov’ëv as the realization of a ’free theocracy’ - a social system based upon Christian principles and thus establishing the Kingdom of God on earth. Solov’ëv’s Slavophile friends warmly sympathized with this vision but remained sceptical about his ecumenical ideas. When Solov’ëv arrived at the conclusion that Russia, in order to fulfil her mission, should recognize the authority of the Pope, his break with the Slavophile circles became unavoidable.

To avoid censorship, Solov’ëv’s vision of ’free theocracy’ had to be expounded in books published abroad, such as *Istoriia i budushchnost’ teokratii (The History and the Future of Theocracy)* (Zagreb, 1887), *L’Idée Russe (The Russian Idea)* (Paris, 1888) and *La Russie et l’Église Universelle (Russia and the Universal Church)* (London 1889). In Russia these books were received as Roman Catholic propaganda and consequently often aroused hostility. This was not just a misunderstanding; in 1886 Solov’ëv recognized the Pope as supreme judge in matters of religion, and three years later, in *Russia and the Universal Church*, publicly defended this view. It was known, as well, that his vision was supported by the influential Croatian bishop, Josip Strossmayer (who commended Solov’ëv’s ideas to Pope Leo XIII). On the other hand, however, it needs to be stressed that the French Jesuits ceased to support his project on the grounds of its heterodox ideas (especially in the theosophical part of his views).

Solov’ëv’s conception of ’free theocracy’ rested on his view that the structure of legitimate authority had to be triune, corresponding to the three persons of the Holy Trinity. The Kingdom of God on earth, he argued, will be established when humanity becomes unified under the authority of one high priest (representing God the Father) and one emperor (representing the Son), and when genuine prophets, ’the free breath of the Holy Ghost’, appear constantly among the common people to mediate between the temporal and spiritual authorities. This vision was to materialize in the unification of the human race under the spiritual rule of the Pope and the secular rule of the Russian tsar. In this way Russia would take up the old idea of a Christian Empire, formulated by Constantine the Great, Charlemagne and the greatest Catholic writer, Dante Alighieri. In the realization of this task Russia would be supported by the two ’theocratic nations’ which shared in her historical fate: the Jews and the Poles.

Solov’ëv did not proclaim that members of the Orthodox Churches should simply convert to Roman Catholicism. On the contrary: he combined sharp criticism of religious particularism (or even the nationalism of the Greek and Russian clergy), with an emphasis on the unique spiritual values of Eastern Christianity. The Roman Pope was, in his view, the legitimate head of the Universal Church, but this did not mean equating the Universal Church with the Roman Catholic Church. The Universal Church was a broader notion, embracing both Western and Eastern Christianity. Solov’ëv concluded from this that the recognition of the authority of the Pope would liberate the Orthodox Church from humiliating dependence on the imperial power without entailing any danger for the existence of the distinctively Eastern religious culture.

Solov’ëv saw no contradiction between his theocratic ideal and his growing sympathy with liberal political ideas. He stressed that his theocracy was to be ’free’, hence liberal and universalist, and thus incompatible with nationalism (which he distinguished from patriotism). In a series of articles published in the liberal *Vestnik Evropy (European Messenger)* and reprinted in the book entitled *Natsional’nyi vopros Rossii (The Problem of Nationalities in Russia)* (two volumes, 1891), he firmly condemned all forms of persecution and discrimination against national and religious minorities.

At the beginning of the 1890s Solov’ëv became disillusioned with theocratic utopianism and as a result drew even

closer to the liberals. But he remained faithful to the view that, in order to resist the evils of national egoism, Russia should embrace liberal principles without abandoning her imperial calling.

4 Ethics, philosophy of law and theory of knowledge

The de-utopianization of Solov'ëv's thought brought about a marked secularization of his views on ethics. His comprehensive treatise *Opravdanie dobra (The Justification of the Good)* (1897) was to be a system of independent ethics, in the sense of the independence of ethical conduct from metaphysical theories and religious dogmas. It is divided into three parts: (1) The Good in Human Nature, (2) The Good from God and (3) The Good in the History of Humankind. In Part I Solov'ëv tried to give his ethic empirical foundations by deriving it from feelings of shame, compassion, and religious adoration; he stressed, however, that empirical ethics must be supplemented by rational ethics whose highest principle is the categorical imperative of Kant (see Kant, I. §9). In Part II he dealt with moral progress, explaining it as the development of man's divine features, or the realization of the idea of Godmanhood. The two parts of this process were (1) the realization of Godmanhood in an individual, and (2) the realization of Godmanhood in the collective life of humankind.

With this conclusion Solov'ëv passed to Part III of his ethical system - to 'objective ethics', or the institutionalized forms of the historical education of humanity, as opposed to 'subjective ethics', concentrating on purely individual perfection and salvation. The emphasis on objective ethics, embodied in the institutions of the state, was also an essential feature of his theocratic ideal. But the difference was profound: according to Solov'ëv's objective ethics Church and state were to be formally separated and the task of securing the moral character of social and political life was to be fulfilled not by a theocratic government, but by an impersonal system of legal rules. In this way the realization of the idea of Godmanhood in history was made dependent on man's maturity, on his full moral autonomy, incompatible with any form of tutelage in the spiritual sphere.

This Kantian reinterpretation of the idea of Godmanhood found expression in Solov'ëv's philosophy of law, elaborated in the relevant chapters of *The Justification of the Good* and in a separate booklet *Law and Morality* (1897). This legal philosophy, defining law as the compulsory and enforceable minimum morality, was the earliest Russian variant of a 'new liberalism' concerned not only with negative freedom, but with positive freedom as well. In Solov'ëv's conception, the modern rule-of-law state was given a new function: that of ensuring for everyone a minimum of positive freedom and justice, that is equal opportunity and the minimum of welfare necessary for a 'dignified existence'. Solov'ëv saw 'dignified existence' as a new human right, as something legally claimable, and interpreted it very broadly. In his view, 'the right to a dignified existence' included not only rights to employment, to proper working conditions and proper earnings, but also to rest and free time. He anticipated modern ecological movements by postulating that enterprising individuals should not be given a free hand in conquering and exploiting nature, because the preservation of the natural environment is a necessary condition of a worthwhile existence.

Solov'ëv made it clear that even the best realization of this ideal would not have amounted to the millenarian Kingdom of God. He stressed that he did not want to legislate absolute morality but only to give legal backing to a moral minimum.

Another consequence of the de-utopianization of Solov'ëv's views was his increased willingness to treat interest in theoretical questions as autonomous, independent of social and religious concerns. This shift in his thought is shown in his three epistemological articles under the title *Osnovy teoreticheskoi filosofii (Foundations of Theoretical Philosophy)* (1897-9). His reflections on epistemological issues led Solov'ëv to reject the Cartesian tradition of 'spiritualist dogmatism' that assumed the substantiality of the knower. He also substantially modified his conception of 'integral knowledge' by de-emphasizing its mystical character and stressing instead 'purposeful cognition', or a 'vital act of decision' that directs the consciousness towards absolute truth and transforms immediate sense impressions into the material of the complex process of active cognition. To some extent the concept of 'purposeful cognition' recalls the phenomenological notion of 'intention' and the 'intentional act'. Unfortunately, further elaboration of these ideas was prevented by Solov'ëv's premature death.

5 Solov'ëv's continuators

During his lifetime Solov'ëv won recognition in the milieu of professional philosophers grouped around the

periodical *Problems of Philosophy and Psychology*. He had also two direct and very talented disciples, brothers Sergei and Evgenii Trubetskoi. His influence, however, only became widespread, reaching far beyond professional philosophers, in the first decade of the twentieth century, due to the powerful revival of the interest in religious ideas in Russian thought. It is no exaggeration to say that an entire generation of Russian idealist philosophers and religious thinkers was schooled in his philosophy. Sergei Bulgakov, Semën Frank, Father Pavel Florenskii and Lev Karsavin based their work on Solov'ëv's metaphysics of All-Unity and developed different variants of 'Sophiology'. Prince Sergei Trubetskoi made use of Solov'ëv's ideas in his polemics against 'epistemological individualism', in which he referred to the concept of a supra-individual consciousness identified by him with Sophia. The intuitivist Nicholas Lossky tried to use Solov'ëv's ideas in a different way, combining his notion of All-Unity with a monadistic pluralism. Messianic and eschatological motifs in Solov'ëv's thought exercised a strong, formative influence on Nikolai Berdiaev and on the critic and novelist Dmitrii Merezhkovskii who formulated the ideas of a 'new religious consciousness' (see Russian religious-philosophical renaissance §3). Solov'ëv's seminal influence can also be traced in the work of the Russian symbolist poets - Viacheslav Ivanov, Andrei Belyi, and Aleksandr Blok (see Russian religious-philosophical renaissance §4). Solov'ëv's conception of the 'right to a dignified existence' was taken up and developed by Pavel Novgorodtsev, the leading representative of the neo-idealist current in Russian philosophy of law, closely bound up with Russian liberalism (see Liberalism, Russian §3). Another philosopher of Russian 'new liberalism', Sergei Hessen, elaborated a Neo-Kantian reinterpretation of Solov'ëv's philosophy of All-Unity, stressing the idea of the autonomy of different spheres of culture and setting it against utopian motifs in Solov'ëv's thought.

In the Soviet Union interest in Solov'ëv was deliberately suppressed. The first Soviet edition of Solov'ëv's selected works appeared only under Gorbachev's *perestroika*, in 1988. In the West interest in Solov'ëv is still limited but constantly growing. He is best known in Germany, where his selected works were first published in 1914-17 (Jena, three volumes) and 1921-2 (Stuttgart, four volumes), paving the way for the ambitious undertaking of a German edition of his collected works, started in 1953. In France Solov'ëv is known mostly in Catholic circles interested in ecumenical ideas. At the end of 1991 a transnational 'Vladimir Solovyov Society' (with offices in Norwich, Vermont, and in Moscow) was called into being at a meeting in Moscow between American and Russian scholars.

Sophists

The Sophists were itinerant educators, the first professors of higher learning, who appeared in Greece in the middle and later fifth century BC*. The earliest seems to have been Protagoras, who was personally associated with the statesman Pericles. The next most eminent was Gorgias, an influential author and prose stylist. The Sophists succeeded in earning very large sums for their instruction. They lectured on many subjects, including the new natural philosophy, but their most important teaching was in rhetoric, the art of influencing political assemblies and law courts by persuasive speech. In conservative circles their great influence was regarded with hostility, as corrupting the young.*

The term *sophistēs* is an agent noun from the Greek verb *sophizesthai*, ‘to be skilful’ (*sophos*). So a *sophistēs* was originally an expert in any form of wisdom or skill (*sophia*). The term was thus applied to poets, philosophers and sages of all sorts. But by the late fifth century BC it had received a special application to a new class of men: the professional educators, known to Plato and posterity as the ‘Sophists’.

According to Plato, Protagoras (§2) was the first to identify himself as a Sophist and to offer training in public affairs for a fee. He professed to teach men ’to manage their households well and to administer the business of the city’ (*Protagoras* 318e). For this, Protagoras and the other Sophists could expect to be paid handsomely. Their instruction was particularly attractive to ambitious young men in pursuit of a political career. Skill in public speaking was of supreme importance, above all in Athens, where political decisions were made in public assemblies and in very large law courts. Some Sophists, such as Gorgias, claimed only to teach rhetoric, that is, skill in public speaking. Typically, however, the goal of Sophistic training was conceived in terms of civic virtue or excellence (see Aretē). Hence the urgency of the question, much debated in the dialogues of Plato (§11), whether virtue can be taught.

The Sophists were travelling professors who founded no permanent schools. They came from all parts of Greece but were frequently active in Athens, the richest and most powerful Greek city of the time. They were often public figures: Gorgias, Hippias and Prodicus came to Athens as political representatives of their native cities, and Protagoras wrote the lawcode for the Periclean colony of Thurii. Their closest Athenian colleague was Socrates, who was popularly regarded as a Sophist, although he insisted that he was not a teacher and took no fees. But Socrates belonged to the same intellectual circles and was believed to exercise a similar influence on the young (see Socrates §1,2,7).

The content of Sophistic education was very diverse. Although the principal subject was political eloquence, training also included the study of Homer and the other poets as presenting traditional paradigms of excellence. Rhetoric was taught by example, and by memorizing and imitating such display pieces as the *Encomium of Helen of Troy* and the *Defence of Palamedes* by Gorgias, and the ’Choice of Heracles’ by Prodicus. Some Sophists also taught mathematics, astronomy and natural philosophy. All of them were acquainted with, and served to propagate and popularize, the new naturalistic worldview that had begun to replace traditional religious and mythopoetic ways of thought. The new outlook had begun in sixth-century Miletus and been developed by Xenophanes, Heraclitus and Parmenides, as well as by fifth-century cosmologists such as Anaxagoras and Empedocles. This is the world view of the fifth-century Enlightenment, whose influence can be seen in Euripides, Thucydides and many of the Hippocratic treatises (see Hippocratic medicine).

The Sophists played a key role not only in the transmission but also in the development of this new rationalism in the second half of the fifth century. The theological scepticism and epistemological relativism expressed in Protagoras’ thesis that ’man is the measure of all things’ mark a radical break with the traditional Greek worldview centred on the gods. And the psychological cynicism displayed in Gorgias’ defence of Helen of Troy implies a similar alienation from traditional Greek morality. All this lies behind Aristophanes’ hostile caricature of the new education in his comedy the *Clouds*, in the figure of the Unjust Argument who defends adultery and self-indulgence as ’necessities of nature’ and urges his auditor to ’follow nature, frolic, laugh, consider nothing shameful’ (*Clouds* 1075-8).

Aristophanes is alluding here not only to Gorgias’ amoral defence of Helen’s adultery, but more generally to the

antithesis between nature and convention (*physis* and *nomos*) that was made popular in Sophistic rhetoric and used by some of the Sophists to undermine the authority of the traditional moral code, treated now as a mere human convention (see Antiphon; Callicles; Physis and nomos). So in Aristophanes' *Clouds* the pupil of the Unjust Argument will learn 'to despise the established norms (*nomoi*)' and to treat the rule against father-beating as a matter of convention that can be changed by persuasive speech. All of this is presented by Aristophanes as the fruit of the Sophistic enterprise of making the weaker argument the stronger.

Aristophanes is a representative of the popular, conservative reaction against the new rationalism, which was seen as a threat to traditional values. In this regard Socrates and the Sophists were tarred with the same brush, and in the *Clouds* Socrates is in fact presented as the principal Sophist. It was Plato who succeeded in distinguishing the philosophers from the Sophists and thus separating Socrates from the professional educators, despite the fact that both belonged to the new Enlightenment tradition. For Plato, the sophist is a false image or imitation of the philosopher. For Aristotle, the sophist is a specialist in invalid but persuasive argument. It is this Platonic-Aristotelian conception of sophistry that has been transmitted to the present day.

Since the Sophists founded no schools, their influence extended beyond their own lifetime only through their writings and the work of their pupils, notably the rhetoricians Isocrates and Alcidamas, who had studied with Gorgias. Among the followers of Socrates, Antisthenes §1 was also heavily influenced by Sophistic modes of thought, and he too is alleged to have been a pupil of Gorgias, presumably before he attached himself to Socrates.

Sorel, Georges (1847-1922)

The French social theorist Georges Sorel is best known for his controversial work Réflexions sur la violence (Reflections on Violence), first published in 1908. He here argued that the world could be saved from 'barbarism' through acts of proletarian violence, most notably the general strike. This, he believed, would not only establish an ethic of the producers but would also serve to secure the economic foundations of socialism. Moreover the inspiration for these heroic deeds would be derived from a series of 'myths' that encapsulated the highest aspirations of the working class. More broadly Sorel should be seen as an innovator in Marxist theory and the methodology of the social sciences.

Born in Cherbourg,Sorel was educated at the prestigious *École Polytechnique* in Paris before gaining employment as a government engineer. Remaining in this position until 1893, it was not until the late 1880s that Sorel's writings began to appear. Upon retirement he took up residence in the Paris suburb of Boulogne-sur-Seine and thence became a central figure in the intellectual world of the Parisian Left Bank. Associated with the intriguing figure of Charles Péguy, Sorel quickly established a wide range of international correspondents (for example, Benedetto Croce and Antonio Labriola) and over a period of thirty years was intimately associated with an extensive series of reviews that did much to introduce new ideas into France.

Fascinated by what he termed the 'ethics of socialism', it was during a period of intense trade union strike activity and government repression that Sorel published *Réflexions sur la violence (Reflections on Violence)* (1908a). Heavily influenced by Vico, Nietzsche and Bergson (as well as by Marx), Sorel here argued that it would be through acts of violence that the proletariat would establish the economic foundations of socialism while simultaneously engendering a new morality of the producers. If the working class, and more narrowly the revolutionary syndicalist movement, was to be the vehicle of this radical transformation of society, its inspiration was to be a series of 'myths' associated principally with what was characterized as the proletarian epic of the general strike. Arguing against what he termed 'the intellectualist philosophy' Sorel's point was that 'people who are living in the world of "myths" are secure from all refutation' and therefore are capable of heroic deeds. It was such heroism on an almost Homeric scale that was required if the 'total ruin of institutions and of morals' was to be reversed.

To understand why Sorel adopted this stance it is necessary to be familiar with at least two dimensions of his thought. First, an intense moralism characterizes his writings throughout and underpins and explains his frequent changes in political position. Sorel was convinced that he lived in a world of moral decline and decadence and this he came increasingly to associate with the Western bourgeoisie. Sorel's own preference was for what was, in effect, a Catholic and Proudhon-inspired morality of extreme severity, leading him to argue (for example) that the 'world becomes more just to the extent that it becomes more chaste'. Always a pessimist, he saw the image of the Wandering Jew, 'condemned to march forever without knowing rest', as the symbol of man's highest aspirations. What mattered was that the working class should not be contaminated by this decadence.

Second, if Sorel was one of the people most responsible for the introduction of the ideas of Marx into France during the 1890s, then he also engaged in the process of an extensive reformulation and reinterpretation of what he took to be the central tenets of Marxist philosophy. Quickly abandoning the idea that Marx had discovered the laws that 'determined' the development of capitalism, he first redefined Marx's key notions (for example, the theory of value) as metaphysics, then as 'social poetry', before finally hitting upon the idea that they were best seen as 'myths' capable of inspiring action in the proletariat. In political terms this initially meant support for social democracy (and agreement with Eduard Bernstein), but the outcome of the Dreyfus Affair convinced Sorel that the 'revolutionary idea' was indispensable for Marxism. Crucially, however, the revolution (if it ever occurred) was not to take the form of the collapse of capitalism but of the transvaluation of all values (a term he borrowed fromNietzsche to denote his rejection of orthodox Marxism and its emphasis upon economics).

By 1909 Sorel had lost faith in the capacity of the French working class to effect the social transformation he so desired. There followed a brief association with intellectuals on the extreme Right, opposition to the First World War and the plutocratic civilization it represented, before a final enthusiasm for Lenin's Bolshevik Revolution and the hope that this might bring the end of 'the arrogant bourgeois democracies, today shamelessly triumphant'.

Yet beneath this lay a deeper interest in the philosophical issues of the day. Educated in the positivist tradition of Comte, Sorel repeatedly sought to defend science as a progressive, experimental activity while refuting the universalistic claims of the scientism he associated with the positivism he had imbibed in his youth. His extensive writings on both religion and science reveal a thinker determined to defend the validity of our different forms of knowledge, embracing a methodological and epistemological pluralism that would itself avoid the perils of subjectivism. In this he drew inspiration not just from Vico's notion of *verum ipsum factum*, that we can only have knowledge of what we have made ourselves, but in turn from the conventionalism of Poincaré, the intuitivism of Bergson and the pragmatism of William James.

Sôsan Hyujông (1520-1604)

Sôsan was a Korean Sôn Buddhist monk who sought to establish the equality of various ideas and systems. His philosophical perspective conferred equality on Confucianism, Daoism and Buddhism alike, and within Buddhism he denied there was any inherent conflict between the Kyo and Sôn schools. However, he viewed Sôn (meditation) as being the most advanced form of practice.

Sôsan Hyujông, popularly known as 'Sôsan,' was a Korean Sôn (Zen, in Japanese) Buddhist monk of the Chosôn Dynasty (1393-1910) who espoused 'liberal' views. Why were Sôsan's views so liberal? The answer may lie in the fact that he was an extremely pure Sôn monk. True to the spirit of Sôn, he perceived all things and all beings as equal. Perhaps we can clarify this point through the well-known Buddhist simile of an ink-seal, used to stamp three different elements: clay, water and air. In both clay and water, traces of the seal remain, but in air the seal makes no imprint whatsoever. Sôsan was like the air: whatever happened to him, he was not influenced by it but remained the same. This was perhaps his most valuable asset, as it afforded him much flexibility in both thought and action.

Sôsan is important in the history of Korean Buddhism for three reasons. First, during the Japanese invasion of Korea in 1592, he organized an army of Buddhist monks to participate in the country's defence. Though this force helped to repel the invaders, he was later criticized for breaking the Buddhist precept against killing. While believing that his actions had been necessary, Sôsan himself allegedly felt a certain amount of remorse. After the war, King Sônjo recognized his contribution with an award, and the two men subsequently developed a friendship.

Second, Sôsan pioneered an overarching philosophical perspective which stressed the essential equality of all three of the religious systems then active in Korea: Confucianism, Daoism and Buddhism. One commentator has explained Sôsan's view of the relationship of the three religions in terms of rice farming: while the practice of Confucianism is akin to planting the seeds, and that of Daoism is akin to nourishing them, the practice of Buddhism is akin to uprooting sick shoots and replacing them with healthy ones. Sôsan thus viewed all three thought systems as cooperative and complementary, and believed that each should be allowed to perform its own special function free of interference from the others. Due to his influence, communication was greatly expanded among the leading thinkers of his day.

Third, Sôsan espoused a similar doctrine of non-interference within Buddhism itself, particularly in regard to the longstanding antagonism between the scriptural (Kyo) and meditational (Sôn) schools. Denying the view that there was an inherent conflict between these schools, Sôsan instead forged a conceptual link between them by equating Kyo with the Buddha's words and Sôn with his mind. How can they be contradictory, he asked, since both originate from the same source? He did feel, however, that once a practitioner had achieved a firm grasp of scripture he should continue on to the next stage, which was meditational practice. Thus Sôsan still viewed Sôn, or meditation, as the more advanced form of practice. In this sense he deserves to be called a typical Chan master, in the tradition of the Linji school.

Soto, Domingo de (1494-1560)

The sixteenth-century Spanish Dominican, Domingo de Soto, was a mainstay of the Thomistic revival begun at Salamanca by Vitoria. After study at Paris (where he was taught by the nominalist John Major) and Alcalá, Soto taught both philosophy and theology. He was influential within the Dominican Order and the Catholic Church; he served as Emperor Charles V's theologian at the Council of Trent and played an active role in the development of the Council of Trent's teaching on original sin. Besides his theological writings, Soto composed philosophical works chiefly in logic, natural philosophy and juridical theory. In logic, he authored an exposition of the Summulae of Peter of Spain and a commentary, by way of questions, on three of Aristotle's works. His natural philosophy anticipated later scientific approaches, while in his philosophy of law Soto presented a basically Thomistic doctrine updated to confront sixteenth-century issues.

1 Life and works

Born in 1494 at Segovia in Spain, Domingo de Soto studied at the University of Alcalá between 1512 and 1516. In 1517 he received a master of arts degree at the University of Paris, where he came under nominalist influence. Between 1517 and 1519, while teaching philosophy at Paris, he studied theology there, principally under the Scottish master, John Major. At this time he may have attended lectures by Francisco de Vitoria at the Dominican house of St Jacques in Paris. Returning to Spain, he continued the study of theology, as well as teaching philosophy, at Alcalá, where in 1525 he received his doctorate in theology. That same year he joined the Order of Preachers, the Dominicans. From 1525 to 1532 he was teaching philosophy and theology in the Dominican convent of San Esteban at Salamanca. In 1529 he published at Burgos the first edition of his *Summulae*. This work, which he would revise extensively in 1539, was a logic textbook partly based upon the famous *Summulae logicales* of Peter of Spain. In 1532 he assumed the 'Chair of Vespers' in theology at the University of Salamanca, which office he held until 1549. During this period he served two terms as prior of San Esteban.

Soto was chosen by Charles V to be an imperial theologian at the first sessions of the Council of Trent; between 1545 and 1547 he played an active role in the development of the Council's teaching on original sin. He also wrote an important treatise, *De natura et gratia, libri tres (Three Books on Nature and Grace)*, published at Venice in 1547. From 1548 to 1550 he was confessor to Charles V in Germany. At this time Charles offered him the bishopric of his native Segovia, which Soto respectfully but firmly refused. Back in Spain, the following year he presided over the Junta de Vallodolid, made up of fourteen theologians selected to judge the matter of the Spanish conquest of the Indians of the New World. The principal business before the Junta was a debate between the humanist Gino de Sepúlveda, the defender of the Spanish role, and its most severe critic, Bartolomé de las Casas, Bishop of Chiapa in Mexico (see Latin America, colonial thought in §1). Soto composed an objective summary of the debate which presented both positions fairly but did not take sides.

In 1552, Soto succeeded Melchior Cano in the 'Chair of Prime' in theology at Salamanca, a chair earlier occupied by Vitoria. In this position, he continued Vitoria's renewal of Thomism and its development to meet new problems presented by the Reformation, the discovery of America, and the rise of a free-market system in Spain. In 1554 Soto published a third edition of his *Summulae*, in 1555-6 a commentary on the fourth book of the *Sentences* of Peter Lombard, and in 1553-4 his famous *De justitia et jure, libri decem (Ten Books on Justice and Law)*. Retiring from his chair in 1556, he once more became prior of San Esteban, in which office he died on 15 November 1560.

Soto's philosophical work is in three main parts: logic, natural philosophy, and juridical theory or philosophy of law. In addition, his theological writings touch on diverse philosophical issues. For example, in his treatise on nature and grace, he dealt at length with the nature of human beings, the soul's relation to the body, the intellect's need for the senses, and the freedom of the human will *vis-à-vis* the causality of God. At different points in his commentary on the fourth book of the *Sentences*, which is mainly concerned with sacramental theology, he discussed signs and things signified, conditions required for a definition, the existence of accidents in material substances, the possibility of accidents existing without a subject in which they inhere, the transcendental and non-generic character of being as shared between substance and accidents, the immortality of the human soul, as well as the communication of temporal authority by God first to the people and then to the sovereigns they choose.

2 Logic

In logic, Soto's revised *Summulae* of 1539 and 1554 comprises five books, plus two treatises on insolubles and obligations. Book 1 is on terms, which Peter of Spain defined as 'words which are by convention significative'. This occasions for Soto, in Lecture 1 of Chapter 2, an extended treatment of signification and signs. The latter are divided into natural, conventional and customary. Natural signs in turn are divided into formal and instrumental. Book 2 is on propositions. Here he deals with nouns and verbs as they compose propositions. He then treats of definition, division and argumentation. Chapters 5 to 8 of Book 2 treat of categorical and hypothetical propositions, while further chapters cover supposition, relatives, induction, ampliation and appellation. Book 3 concerns the opposition, equipollence and conversion of propositions. Book 4 treats exponible propositions and their species such as exclusives, exceptives, reduplicatives and so on. Book 5 examines the syllogism, its figures and moods, its essential conditions and defects.

In the first volume of his work *In Dialecticam Aristotelis (On the Logic of Aristotle)* (1543), Soto begins with questions about the scientific character and subject matter of logic. Following this he comments on the *Isagōgē* of Porphyry and treats the notions of genus, species, difference, property and accident. In a second volume, he deals with *antepredicamenta* (which are the definitions of equivocal, univocal and analogical terms, the division of terms into simple and complex, and so on), the ten categories of substance and accidents, as well as *postpredicamenta* (for example, opposition and its species). In the same volume, he comments on twenty-seven chapters of Book 1 of the *Posterior Analytics*, raising special questions with regard to science and demonstration. Then more briefly he explains eighteen chapters of Book 2 of the *Posterior Analytics*, without raising any special questions (see Language, Renaissance philosophy of §1; Logic, Renaissance §2; Aristotelianism, Renaissance).

3 Natural philosophy

In his work *Super VIII libros Physicorum Aristotelis (On the Eight Books of Aristotle's Physics)* (1545), Soto was concerned, according to Marcial Solana (1940), not so much to know what Aristotle thought as to know the truth with respect to nature, its principles and causes, movement, place, time, infinity, continuity, and so on. In at least one passage, Soto has, in the estimate of Pierre Duhem (1913), anticipated Galileo (§1) on the free fall of bodies. The core of this passage reads: 'When a body falls from a height through a uniform medium, it is moved with more velocity at the end of its fall than at the beginning. But the motion of projectiles is slower at the end than at the beginning. And in this way the first [motion] "gets faster with uniform acceleration" (*uniformiter difformiter intenditur*) while the second ''declines with uniform deceleration'' (*uniformiter difformiter remittitur*)' (*Super VIII libros Physicorum*, VII q.3). However, Soto did not anticipate the careful experimentation and the mathematics on which the fame of Galileo rests.

4 Philosophy of law

Soto's *De justitia et jure, libri decem* presents a basically Thomistic doctrine updated to confront sixteenth-century issues. In Book 1 he explicates the notion of *jus*, which first means 'law', but also means 'right' in the sense of what is right or just. In this latter sense, *jus* is the object of the virtue of justice. Law is defined as 'an ordinance of reason promulgated for the common good by one who has charge of the republic'. Law is divided into eternal, natural and positive (divine and human). Eternal law is the divine reason which from eternity has ordered all things to their respective ends. Natural law is an impression of the eternal law upon human beings to guide them in ordering their actions to the end for which they were created (see Natural Law §1). The natural law is made up of precepts which are immediately evident and unchangeable and precepts inferred from these as conclusions which are subject to change by addition or by changing circumstances (*mutatio materiae*). Divine positive law comprises prescriptions and proscriptions of the Old and New Testaments. Human positive law is either civil or canon law, plus the law of nations (*jus gentium*). The law of nations is positive law which human beings inasmuch as they are rational have everywhere established for themselves. For this establishment, unlike that of civil law, there was no need of a general assembly or an explicit enactment. Instead, by reason alone, human beings everywhere are in substantial agreement on the main facts of dominion, private property, exchanges, buying and selling, war and peace, slavery in some instances, keeping faith even with enemies, the immunity and protection of ambassadors, and so on. After treating distributive justice in Book 3, Soto deals in Book 4 with commutative justice. Here he looks at ownership and its transfer. In Book 5, he treats injustice of various kinds and its punishment. Here he supports the right of the state to exact the death penalty and to wage a just war. In the remaining books, Soto deals in more detail with property rights and their transfer, partnerships, sales contracts, just prices, deposits, loans,

interest and usury. On numerous occasions he discusses the rights of individuals *vis-à-vis* those of the community (see Law, philosophy of; Political philosophy, history of §8).

Soul in Islamic philosophy

The discussion of the human soul, its existence, nature, ultimate objective and eternity, occupies a highly important position in Islamic philosophy and forms its main focus. For the most part Muslim philosophers agreed, as did their Greek predecessors, that the soul consists of non-rational and rational parts. The non-rational part they divided into the plant and animal souls, the rational part into the practical and the theoretical intellects. All believed that the non-rational part is linked essentially to the body, but some considered the rational part as separate from the body by nature and others that all the parts of the soul are by nature material. The philosophers agreed that, while the soul is in the body, its non-rational part is to manage the body, its practical intellect is to manage worldly affairs, including those of the body, and its theoretical intellect is to know the eternal aspects of the universe. They thought that the ultimate end or happiness of the soul depends on its ability to separate itself from the demands of the body and to focus on grasping the eternal aspects of the universe. All believed that the non-rational soul comes into being and unavoidably perishes. Some, like al-Farabi, believed that the rational soul may or may not survive eternally; others, like Ibn Sina, believed that it has no beginning and no end; still others, such as Ibn Rushd, believed that the soul with all its individual parts comes into existence and is eventually destroyed.

1 The existence of the soul

All Muslim philosophers concerned themselves with the subject of the soul. The most detailed and most important works on this subject are those of al-Kindi, al-Farabi, Ibn Sina and Ibn Rushd. Muslim philosophers recognized that the first issue that confronts the human mind with regard to the soul is its existence. That is why, at the very beginning of his inquiry about the soul in *al-Shifa' (Healing)*, Ibn Sina (§6) asserts that we infer the existence of the soul from the fact that we observe bodies that perform certain acts with some degree of will. These acts are exemplified in taking nourishment, growing, reproducing, moving and perceiving. Since these acts do not belong to the nature of bodies, for this nature is devoid of will, they must belong to a principle they have other than bodies. This principle is what is called ‘soul’.

This argument is intended to prove the existence of the animal soul, which includes the plant soul. The soul is the source of acts performed by the will, not inasmuch as it is ‘a substance’ (an independent entity), but inasmuch as it is ‘the principle of such acts’. The rational soul, on the other hand, need not look outside itself to infer its existence. It is aware of its existence with immediacy, that is, without any instruments. Ibn Sina’s example of the suspended man is intended to prove that the rational soul is aware of itself apart from any body. His argument boils down to the view that, even if the adult rational soul is not aware of anything material, not even its body, it remains aware of its own existence.

2 The nature of the soul

While Islam made it incumbent on Muslim philosophers to occupy themselves extensively with the study of the soul and to make certain statements that in some cases appear consistent with Islamic beliefs, Greek philosophy had the upper hand in forming the real convictions of Muslim philosophers with regard to the nature of the soul. Unless otherwise specified, reference to the soul here is limited to the terrestrial soul to the exclusion of the celestial one, since Muslim philosophers concerned themselves primarily with the former. It must be pointed out at the outset that ‘soul’ (*nafs*) was used in more than one sense in Islamic philosophy; the term was used to refer to the plant or vegetative part of a living being, the animal or sensitive part, the rational part and finally the totality of all three parts. The first two are the non-rational soul and the totality is the human soul. To add to the confusion, ‘human soul’ is used only in the sense of this fourth type of soul. The plant, animal and rational souls are also called powers or parts of the soul. Only from the context can one understand whether a Muslim philosopher was using ‘soul’ in the broad sense to mean the human soul (the totality of the parts of the soul), or in the narrow sense to mean a specific part of the human soul.

Inasmuch as it has a certain relation to a body, the soul is a form for that body, that is, the perfection of that body. It is a form because a natural body is composed of matter and form, which in the case of animals are body and soul. Since it has been shown that the soul is the source of will and therefore is not matter, it remains a form. Perfection is of two types, primary and secondary. A primary perfection is what makes a thing actually a species,

as shape does for the sword, or a genus, as sensation and movement do for animals. A secondary perfection is an act necessitated by the nature of the species or genus, such as cutting for the sword and touching for animal. The soul is a primary perfection of a natural body capable of performing the secondary perfections necessitated by this primary perfection. Together with its body, the soul constitutes a material substance. This substance can be the subject of plant, animal or human life.

The soul is a perfection inasmuch as it makes a natural body into a plant, an animal or a rational being. However, to define the soul as a perfection does not give us a clue as to what the soul is in itself, but only inasmuch as it has a relation to the body. The body is, therefore, an essential element in the definition of the soul. Without relating to a body, the thing we call ‘soul’ is not a soul and does not require the body as an essential part of its definition. Note, however, that in spite of this assertion, perhaps for the lack of any better term, Muslim philosophers use ‘soul’ also to refer to the rational soul after it separates from the body and reaches a complete state of purity from matter.

In its first or lowest stages of relating to the body, the soul is the plant soul, which is a primary perfection for an organic natural body inasmuch as this body can take nourishment, grow and reproduce. The plant soul is the power human beings and other animals share with plants. If the body with a soul is an animal, the soul develops into the animal soul, which is a primary perfection for an organic natural body inasmuch as this body has sensation and movement through will. While this soul includes the plant soul, it has also a sensitive power and a locomotive one. The sensitive power has both external and internal senses. The external senses are, in priority of existence, touch, taste, smell, hearing and sight. The first three are said to be necessary for survival and the last two for well being. In *Talkhis kitab an-nafs (Middle Commentary on Aristotle’s On the Soul)*, Ibn Rushd (§3) asserts that the five external senses may be in potentiality, as in infancy and sleep, or in actuality, as in daily seeing or hearing. He also argues that there cannot be any external sense other than these five because there would be no function for it, since there is no external sensation other than the objects of the five senses mentioned above. Most Muslim philosophers mention three types of internal senses: common sense, imagination and memory. Ibn Sina (§3) enumerates five internal senses: common sense, representational power, imagination, estimative power and memory. On the whole, the philosophers agree on the function of the common sense, imagination and memory; the function that Ibn Sina limits to the representational and estimative powers, other Muslim philosophers allocate to the imagination.

The common sense is an internal power in which all the objects of the external senses are collected. Contrary to the external senses, which can grasp only one type of sensation, as sight grasps light and hearing grasps sound, the common sense can grasp all external sensations, such as that honey is of such and such a colour, texture and smell. The representational power preserves the sensations of the common sense even after sensible things disappear. The imagination selects at will to combine some of the objects of the representational power with each other and to separate the rest. It makes its judgment about external things, but in the absence of these things. That is why it functions best when the external senses, which represent external things, are not at work, as in sleep. Ibn Rushd points out that animals such as worms and flies that do not act except in the presence of sensible things are devoid of imagination. The imagination is called such inasmuch as it is an animal instrument; it is called cognitive inasmuch as it is a rational instrument. The estimative power grasps non-sensible notions of sensible things, such as the sheep’s notion that the wolf is to be avoided. This notion is about a sensible thing but is not grasped through the external senses, as is the colour or shape of a wolf. Memory preserves the notions of the estimative power. The imagination acts on the objects of memory in the same way it acts on those of the representational powers. Like the objects of the external senses, those of the internal senses are particular and material. The difference is that they can be experienced in the absence of external things and are to some degree abstracted from matter.

The locomotive power branches into that which causes movement and that which actually moves. The former, the desiderative power, subdivides into the appetitive and the irascible. The appetitive causes movement toward what is imagined to be necessary or beneficial in the pursuit of pleasure. The irascible causes avoidance of what is imagined to be harmful or an impediment in the pursuit of dominance. The power that actually moves uses the nerves to relax the muscles at the demands of the appetitive power or tighten them at the demands of the irascible one.

3 The rational soul

The rational soul, which is defined as a primary perfection for an organic natural body inasmuch as this body can

act by rational choice and grasp the universals, is divided into the practical and the theoretical intellects. The practical intellect seeks knowledge in order to act in accordance with the good in its individual body, its family and its state. It must, therefore, know the principles for properly managing the body, the family and the state, that is, ethics, home management and politics. The practical intellect is the rational soul turning its face downward. The function of the theoretical intellect is to know just for the sake of having the universals (the realities or natures of things). Some of these natures, such as God and the intellect, cannot attach to movement; knowledge of them is metaphysics. Other natures, such as unity, can attach to movement but do not; knowledge of them is mathematics. Still other natures, such as humanity and squareness, can attach to movement either in reality and thought, such as humanity, or in reality but not in thought, such as squareness. Knowledge of these is physics.

The theoretical intellect is the rational soul with its face upward. The practical intellect looks up to the theoretical one and moves its body accordingly. In this, the practical intellect is similar to the celestial soul that looks up to the intellect of its sphere and moves its sphere accordingly. Thus, like the celestial soul, the practical intellect is the link between intellect as such and matter.

On the whole, Muslim philosophers followed al-Kindi's division of the theoretical intellect into the material intellect (*al-'aql al-hayulani*), the habitual intellect (*al-'aql bil-malaka*), the actual intellect (*al-'aql bi'l-fi'l*) and the acquired intellect (*al-'aql al-mustafad*). The material intellect is a blank slate with the potentiality for grasping the intelligible forms or universals. Ibn Sina points out that it is referred to as material, not because it is actually material but because it resembles matter in accepting the form. The habitual intellect grasps the universals, as one acquires the skill to write; in other words, this intellect has the ability to use the universals but does not always do so. The actual intellect grasps the universals in actuality and is always ready to use them. While Muslim philosophers differed slightly with regard to their accounts of the acquired intellect, their general view is that it is the highest human state, the point of contact with the divine, the agent intellect (the intelligence of the moon, the lowest celestial intellect), which makes it possible for the theoretical intellect to acquire the universals in the purest form (see Epistemology in Islamic philosophy §4).

4 The ultimate objective of the soul

Al-Farabi asserts that even though the soul is of different parts, it is a unity with all its parts working for one final end, happiness. While the plant soul, for example, serves a specific function, it also serves the powers that are higher than it in rank, the animal powers. Without nourishment, growth and reproduction, the animal powers cannot perform their necessary functions. Similarly, while the function of the animal powers is to have sensation and movement, by performing this function they also promote the functions of the powers above them, the rational ones. The operations of the animal powers, especially those of the senses, are particularly important for the attainment of the final end. The external senses strip the forms from material objects and convey them to the internal senses. The more they are transferred internally, the less mixed with matter do they become. Since the innermost sense they reach is the imagination, they are there in their purest material existence (see Imagination).

The role of the objects of the imagination is not always clearly defined in Islamic philosophy. Occasionally it is said by somebody like Ibn Sina to be one of preparation for the theoretical intellect to receive the universals from the agent intellect. At other times Ibn Sina, like other Aristotelians such as Ibn Rushd, takes these objects to be the ingredients out of which the universals are made after the last process of purification (see Epistemology in Islamic philosophy). It seems, however, that in either case the light of the agent intellect is needed to complete the process. In the former case, this light gives the intelligible forms to the theoretical intellect when this intellect is prepared. In the latter case, it sheds itself on the objects of the imagination, which are then reflected on the theoretical intellect without their matter. Since the theoretical intellect is in its first stages in potentiality, it cannot act on the objects of the imagination directly; hence the need for the agent intellect, which is pure actuality. The role of the practical intellect in all this is to put order into the body. This sets free the theoretical intellect from preoccupation with the body and helps the powers whose function is necessary for theoretical knowledge to function unhampered.

Muslim philosophers adhered to the view that the acquired intellect is one with its objects, for they thought the knower and the known are one, as did their Greek predecessors. This means that the highest human state is one in which unity with the universals or the eternal aspects of the universe is reached. This state is described as happiness because in it eternity, an aspect of the objects of the acquired intellect, is attained.

5 Eternity of the soul

When Muslim philosophers assert that the soul comes into existence simultaneously with the coming into existence of the body, some, such as Ibn Sina (§6), who believe that the rational soul is in essence non-material, are thinking only of the non-rational soul. Others, such as Ibn Rushd (§3), who believe that the rational soul is originally not separate from matter, contend that the whole human soul comes into existence. The latter believe that since the rational soul grasps the universals from particular sensibles, and since such sensibles are material and have a temporal beginning, this soul must also be material and must have a temporal beginning. Those who attribute non-materiality to the essence of the rational soul, such as al-Kindi and Ibn Sina, assert that this soul pre-exists the body. While all of them agree that the non-rational soul is destroyed after the destruction of the body, they differ with regard to the end of the rational soul.

Al-Kindi and Ibn Sina, for example, strongly adhere to the view that all rational souls are indestructible because by nature they are simple. Al-Farabi reminds us that the reason for eternal existence is the rational soul's knowledge of the eternal aspects of the universe. From this he draws the conclusion, as did Alexander of Aphrodisias before him, that only those rational souls that have this knowledge at their separation from the body are indestructible. Other rational souls are eventually destroyed. Ibn Sina finds in the grasping of the universals the grounds for happiness, not the eternity of the soul. Ibn Rushd seems to hold that only the acquired intellect can be indestructible; but the acquired intellect, he argues (as does his teacher Ibn Bajja), is divine and numerically one in all. Ibn Rushd was attacked for this view because it denies eternal existence of individual souls (see Averroism; Soul, nature and immortality of the).

Soul, nature and immortality of the

For the Greeks, the soul is what gives life to the body. Plato thought of it as a thing separate from the body. A human living on earth consists of two parts, soul and body. The soul is the essential part of the human - what makes me me. It is the part to which the mental life of humans pertains - it is the soul which thinks and feels and chooses. Soul and body interact. Bodily states often cause soul states, and soul states often cause bodily states. This view is known as substance dualism. It normally includes the view that the soul is simple, that it does not have parts. If an object has parts, then one of those parts can have properties which another part does not. But for any experience that I have, an auditory or visual sensation or thought, it happens to the whole me. Plato also held that at death, soul and body are separated; the body decays while the soul departs to live another life. Aristotle, by contrast, thought of the soul simply as a 'form', that is, as a way of behaving and thinking; a human having a soul just is the human behaving (by moving parts of the body) and thinking in certain characteristic human ways. And just as there cannot be a dance without people dancing, so there cannot be ways of behaving without embodied humans to behave in those ways. Hence, for Aristotle, the soul does not exist without the body.

Christian theology, believing in life after death, found it natural to take over Plato's conception of the soul. But in the thirteenth century, St Thomas Aquinas sought to develop an Aristotelian conception modified to accommodate Christian doctrine. The soul, Aquinas taught, was indeed a form, but a special kind of form, one which could temporarily exist without the body to which it was naturally fitted. It has always been difficult to articulate this view in a coherent way which makes it distinct from Plato's. Descartes restated Plato's view. In more modern times, the view that humans have souls has always been understood as the view that humans have an essential part, separable from the body, as depicted by Plato and Aquinas. The pure Aristotelian view has more normally been expressed as the view that humans do not have souls; humans consist of matter alone, though it may be organized in a very complicated way and have properties that inanimate things do not have. In other words, Aristotelianism is a kind of materialism.

If, however, one thinks of the soul as a thing separable from the body, it could still cease to exist at death, when the body ceases to function. Plato had a number of arguments designed to show that the soul is naturally immortal; in virtue of its own nature, because of what it is, it will continue to exist forever. Later philosophers have developed some of these arguments and produced others. Even if these arguments do not show it (and most philosophers think that they do not), the soul may still be naturally immortal; or it may be immortal because God or some other force keeps it in being forever, either by itself or joined to a new body. If there is an omnipotent God, he could keep it in existence forever; and he might have revealed to us that he is going to do so.

1 The existence and nature of the soul

The form of a thing is its shape, appearance, pattern of reaction, and (in the case of a living thing) its way of changing over time and acting, in fact, all the properties that make it the kind of thing it is. The form of a living thing is, for Aristotle, its soul. Plants have 'vegetative' souls, animals have 'sensitive' souls and humans have rational or intellectual souls; a human soul is not just a way of behaving publicly, but also a way of thinking. Forms for Aristotle are universals, in the sense that the same form can be instantiated in many different things. The form of a table, for example, can be instantiated in many different tables. What individuates, what makes the particular table the one it is, is the matter of which it is made. So too, claims Aristotle, what makes a particular human the one they are is the matter of which they are made. No form, he claims, can exist apart from the thing (a particular substance) in which it is instantiated. So a human soul cannot be separated from its body. At least, a whole soul cannot be separated, for Aristotle considers that a soul has parts, and he adds (*On the Soul* 413a) that some parts of the soul may be separable. He may have in mind the part or parts responsible for thought.

Aquinas (§10-11) claimed that the soul does not need any bodily organ for thinking, and that is a main reason why he supposes that the whole soul can continue to exist without a body. In accord with the normal articulation of the Christian doctrine of life after death, Aquinas holds that the soul does continue to exist on the destruction of the body until it is reunited with it in the general resurrection. But what survives, claims Aquinas, is not the whole human being, but that essential part of it with limited functions, whose nature it is to be united with the body, and make it live and have its normal human operations of thought, perception and bodily action. Yet what makes such

a separated soul my soul as opposed to yours? This question cannot be answered within a pure Aristotelian scheme. For Aristotelian forms are universals. There is just the form of humanity, which can be instantiated in many different individuals, and the separated soul is not united with matter. Aquinas says that each form has an ‘inclination’, is ‘fitted’, to be reunited with a certain body, the one from which it has been separated. Duns Scotus objected to this answer on the ground that there cannot be a bare inclination; an inclination has to be grounded in some actually existing feature of the soul. To take a modern analogy, if some substance has an inclination to liquefy at a certain temperature, that must be grounded in its chemical constitution. Hence Scotus holds that souls are not mere universals, but individual forms or essences, that is, that there is an essence of Socrates as well as of humanity. Anyone who holds that souls can exist separately from bodies must give an account of what makes a soul this particular soul, and the same soul as that of some earlier person. For Plato and for Descartes, this is something ultimate, just as perhaps what makes this chunk of matter different from that chunk of matter is something not analysable further. So too for Scotus, even though he thinks of souls as forms of bodies (*Ordinatio* II, d.3).

If Aquinas’ view is to be spelled out coherently, it must be done in the same way. What did happen to a soul in the past, namely that it was united to a certain body, and will happen to it in future cannot make it the soul it is now. That must be something internal to it now. Religious believers who believe that humans can exist without their bodies, even if only temporarily, must hold that. So too must any believer who holds that there is life after death, even if souls do not exist separately from bodies. For if I come to live again, the question arises as to what makes some subsequent human me, for my body will be largely if not entirely destroyed. If the answer is given that (most of) the atoms of my original body will be reassembled into bodily form, there are two problems. First, many of the atoms may no longer exist; they may have been transmuted into energy. And second, what proportion of the atoms do we need? Sixty per cent, seventy per cent, or what? If it is mere atoms which make some body mine and so some living human me, then no body will be fully mine unless it has all my atoms. Yet some of my atoms, even if not destroyed, will have come to form other human bodies. It will be a matter of degree whether a human survives, unless what makes a human the individual human they are is something other than the body, namely the soul (see Resurrection).

But why suppose that there is a separate soul? Descartes (§§5, 8), in his *Meditations*, gave a famous argument which must be the basis of any justification of substance dualism. He argues that I know infallibly that I exist as a thinking thing, but I do not know infallibly that I have a body; maybe that is all a dream. Hence the body is a separate thing from what is essential to me, namely my soul. A traditional criticism of this argument is that the mere fact that I do not know infallibly that my body exists does not show that it is separable from me; maybe I do not know what is involved in my present existence. After all, the argument has the same form as this clearly invalid argument: I know infallibly that I am Bloggs; I do not know infallibly that I am the son of John and Mary; hence the son of John and Mary is not the same thing as Bloggs. The argument can, however, be rephrased to meet this objection, not as an argument from knowledge and ignorance, but as one from logical possibility and impossibility. Descartes, in writing of what is ‘imaginable’, is often near to phrasing the argument in this way. Here is a rephrased version:

(1) I exist as a thinking thing now.
(2) It is logically possible that I go on thinking and so existing, even if my body is suddenly destroyed (and this remains logically possible, whatever else might be the case now inside or outside my body compatible with my existing now as a thinking thing).
(3) It is not logically possible that any thing continue to exist unless some part of it continue to exist.

Hence I must already have another part beside my body, namely my soul. (For a more detailed presentation of this version of Descartes’ argument, see Swinburne [1986] 1997: 145-60, 322-32.)

Most objectors to the argument in this form will deny (2) (see, for example, Shoemaker and Swinburne 1984: 141-8). They would claim that it is not logically possible that I survive without my body. It certainly seems logically possible. Our only grounds for supposing something to be logically possible are that we can make sense of it; we can spell out what it would be like for it to be true. Our only grounds for supposing something to be logically impossible are that we can derive a contradiction from it. It does look as if each of us can tell a coherent story of losing our body and yet continuing to think, and it does not look as if there is an obvious contradiction

involved. So to some philosophers it looks as if the conclusion is sound.

Some claim that the causal interaction which substance dualism postulates between the soul and the body is unintelligible unless we can have some grasp of a mechanism through which brain states cause soul states and vice versa. A defender of substance dualism will respond that we often know very well that certain states cause others without having the least idea how this could occur. Before the theory of electromagnetism was developed, people knew that the motion of a magnetic charge caused an electric current, but had no idea how these very diverse states could influence each other.

2 The immortality of the soul

Even if the soul is simple and separable from the body, it does not follow that it will continue to exist after death, let alone exist forever with a mental life, with thoughts, feelings and sensations. It might instead exist in the way that our souls exist while we have a dreamless sleep. There have been a large number of arguments for the natural immortality of the soul, purporting to show that it is the nature of the soul to be immortal; it will naturally go on forever, without God or any external agency needing to intervene to give it special powers to continue in existence. Most of these are arguments which try to show that the soul has such a peculiar nature that the normal forces which cause things to cease to exist would not affect it.

One well-known argument is that given by Plato (§§10-11, 13) (*Phaedo* 78b) and repeated by, among others, Berkeley (§8) (1710, section 141) and Joseph Butler (§6) (1736 I, ch. 1), from the simplicity of the soul. It runs as follows. We only know of things ceasing to exist when they have parts; and they cease to exist only when the parts are separated from each other. A house ceases to exist when the bricks are taken away from each other. But the soul has no parts, and so we know of nothing which in the normal course of things would cause it to cease to exist, barring divine intervention. So it is reasonable to suppose that it is naturally immortal. But this argument is weak. We do know of things ceasing to exist without any parts being separated from each other. An atom ceases to exist when it is turned into energy. Further, it does look as if the functioning of the soul, its having a mental life, depends on the functioning of the brain. (Does not damage to the brain render a person un-conscious?) We need more positive argument to show that the soul could function without the brain sustaining it. And if it turns out that the soul is incapable of functioning without the brain, why suppose that it even exists?

Plato gives several other arguments for the natural immortality of the soul. They include the argument (*Phaedo* 73a-78a; *Meno* 81b-86b) that humans know many things and have many concepts which they have not learned or acquired on earth. In the *Meno*, Plato describes a slave-boy being led by Socrates to assert various truths of mathematics which no one has taught him. Hence, Plato argues, he must have learned them in a previous existence. But if souls exist before birth and through a life of embodiment on earth, it is natural to suppose that they will continue to exist after death. An objector, however, may reasonably argue that the slave-boy did not know the truths in question until Socrates helped him to become aware of them. The argument from pre-existence did not appeal to Christian philosophers, for Christians have normally held that souls come into existence at conception or birth, though they continue to exist after death. Aquinas appealed to the fact that humans naturally desire to exist forever and that ‘it is impossible that natural appetite should be in vain’ (*Summa contra gentiles* II, 79.6). Yet it is far from obvious why that is impossible. He also appealed to the ability of the soul to ‘apprehend incompatible things’, that is, to understand the eternal truths of mathematics and to have contact with God, as showing that the soul’s own nature is ‘incorruptible’, or naturally immortal (*Summa contra gentiles* II, 79.5). But it is in no way obvious that the finite cannot understand the infinite or that the mortal cannot understand the immortal.

Arguments to the *natural* immortality of the soul are very unappealing today. Some philosophers find arguments to show that the world is such that something external to the soul will guarantee its immortality more persuasive. An argument of Kant captures much more ordinary thinking. It is not strictly speaking, Kant claims, a theoretical argument which proves that the soul is immortal, but a ‘practical argument’ to this effect: we are obliged to act morally, and it only makes sense to do so if we suppose that we, and so our souls, will continue to live forever. Kant regards the various moral obligations under which we stand as different aspects of the obligation to realize the supremely good state of affairs, the *summum bonum*. The *summum bonum* involves our own moral perfection, something towards which we make only slow progress in this life and need endless duration finally to achieve. For moral actions to make sense, we must regard the *summum bonum* as attainable and so regard ourselves as having an endless life. Kant backs up his argument with the further consideration that the *summum bonum* requires that

happiness be in proportion to good moral behaviour, both for ourselves and others. But in this world the good are not always happy. So again for the *summum bonum* to be attainable we need another world in which 'the greatest happiness is… combined…with the highest degree of moral perfection' (Kant 1788, bk 2, ch. 2, section 5). This, Kant claims, requires the operation of God, who alone can bring about such coincidence. Now Kant has a very high conception of the status of moral obligation. Others may not regard its claims so highly. Yet even if we conceive of it as Kant did, it is in no way obvious that to make sense of our doing some moral action, we need to think of it as a step towards our own moral perfection which will eventually be achieved. When conscious of an obligation to help the starving, I give money to a charity; the point of my action is achieved by my giving the money, independently of whether it improves my character. Likewise its purpose is achieved whether or not I am the happier for achieving it. Holiness of will combined with supreme happiness may be good, but acting morally seems to have its own point quite apart from whether all that results from it. Moral actions are in general fully worth doing for totally mundane reasons, even if there are also reasons connected with an after-life for doing them.

Kant's argument has very considerable similarity to the argument of Eastern religions from the law of karma, which they affirm to be a basic principle governing the universe, that all actions get their proper reward (see Karma and rebirth, Indian conceptions of; Reincarnation). Good actions lead to happiness, and bad actions to unhappiness. Since so often this does not happen to a soul during a given earthly life, it must have another life in which morality and reward can be evened out. Although karma does not require another life on this earth, Eastern religions believe that we are normally reincarnated on earth. The good are reincarnated in more desirable states; the good poor man has a more wealthy next life, and the bad poor man may be reincarnated as a mere animal. But Eastern religions do not all hold that this necessarily goes on forever. Buddhism claims that our supreme goal should be to break the cycle of death and rebirth, by living such holy lives that after death we are not reincarnated at all, but depart to *nirvāṇa* (nothingness). It is disputable whether this means 'annihilation' or, on the contrary, a totally blissful state (see Nirvāṇa). However, before we could accept this argument, we would need good grounds for believing that the law of karma operates.

If the soul is not naturally immortal, then the action of some supernatural law (karma) or agent (God) is required to make it immortal. Much Christian tradition affirms that the free action of God is required for this purpose and that he is under no obligation so to act. In that case, in order to have grounds to believe in immortality, we will need his assurance that he will so act. At this point Christian tradition normally produces, not a Kantian argument, but the claim that it is an item of revelation. God has told us that he will so act, that he will bring the dead to life again - the good dead to an everlasting good life, and the bad dead to an everlasting bad life. (There are, however, differences within Christian tradition about what will happen to the bad, and to those who die before they become clearly good or bad (see Heaven; Hell; Limbo; Purgatory; Revelation §§2-3).)

As well as such very general arguments for life after death, there are some empirical arguments. Eastern religions occasionally produce children who claim to be able to recall events of a previous life, events which they could not have known to have happened by any normal means, but which subsequent investigation reveals to have happened. Some child describes the house at some place where 'he' lived in his previous life, and then such a house is found. But there are doubts about the worth of such evidence. Relatively few children make such claims; the story which they tell about the previous life can be vague; and there are doubts about whether ordinary means of their having obtained the information about that life have really been excluded. Then there are arguments from what mediums declare is told to them, while they are in a trance, by persons already dead. The evidence that those persons give is supposed to be the knowledge that mediums acquire of details of those persons' past lives, which, it is claimed, they could not have acquired by any normal means. But there are similar doubts about the worth of evidence of this kind. The knowledge acquired may be vague and might have been obtained by some normal route. Even if these doubts could be satisfactorily resolved, a hypothesis of some abnormal way of acquiring information about the past might seem less radical than a hypothesis of the present existence of persons who have died. Finally, and most interestingly, there has been the discovery of 'after-death experiences'. Some ten to fifteen per cent of subjects resuscitated after being clinically as good as dead report having had 'transcendental experiences' during the period in which they were virtually dead. These experiences consist of a very vivid awareness of approaching a border or frontier and seeing into a strange, normally immensely pleasing world and then being called back. This coincidence of kinds of experience among people of various backgrounds is interesting; but the experiences have relatively little common detail, so as hardly to provide by themselves very strong evidence that what was observed

was really there. These observations would require support from other considerations. In any case, none of the empirical evidence by itself gives any reason at all for supposing the subsequent existence to be everlasting.

South Slavs, philosophy of

Philosophy as a distinct intellectual activity emerged in the coastal towns of the Adriatic during the Renaissance. Philosophers from this area wrote in Latin and taught philosophy in Italy, Germany and Austria. The first popular philosophical works in the vernacular did not appear until late in the eighteenth century, and it was almost one hundred years later that the first chairs in logic and philosophy were founded in the universities. Academic philosophy, usually derived from German or British models, was thus brought into the intellectual life of South Slavs. Local academic philosophers, mostly educated in Germany, brought home a variety of philosophical approaches, and by the early twentieth century many schools of thought flourished: Neo-Kantianism flourished in Beograd, while Neo-Thomism was particularly strong in Ljubljana and Zagreb (until 1941 the Meinongian phenomenological approach also flourished in Ljubljana). In their quest for originality, local philosophers constructed various eclectic philosophical systems.

The Soviet Marxism-Leninism, imposed in all Yugoslav universities after 1945, was replaced in the late 1950s by a Neo-Marxist approach based on the concept of praxis. This was a concept of a purposeful human activity which, among other things, results in social change (for example, the development of socialism). These Neo-Marxists engaged in vigorous debates on the nature of truth and knowledge, on human freedom, alienation, socialism and humanism as well as on social and political issues. Their work reached an international audience through the international journal Praxis*, published in Zagreb, and through their international summer school of philosophy at Korčula. As their support for the Yugoslav communist regime turned into open criticism, the regime halted the publication of* Praxis *and in 1974 forced the Beograd Neo-Marxists from their teaching posts.*

The Neo-Marxist interest in non-Marxist philosophy facilitated the reception of various non-Marxist approaches. From the early 1960s, existentialism, structuralism, hermeneutics and phenomenology - in particular the philosophy of Heidegger - exerted considerable influence on Neo-Marxists as well as on philosophers who had gradually abandoned this approach. In the early 1970s, a younger generation of thinkers in Beograd, Zagreb, Ljubljana and Zadar developed an interest in analytic philosophy. Since that time no approach or trend in philosophy has emerged as the dominant one in any of the academic centres in the countries which were formerly part of Yugoslavia.

1 Philosophy in Latin

Until the Renaissance, philosophy among the South Slavs (on the territory of the former Yugoslavia) was practised only within the theological framework of Roman Catholicism and Eastern Orthodoxy. In the fifteenth century, the Ottoman conquest and the resulting intermittent warfare had greatly impeded intellectual activity. At the same time Renaissance humanism penetrated the coastal towns of the Adriatic (which were not exposed to the Ottoman onslaught). In the Republic of Ragusa (Dubrovnik) especially, an indigenous literature flourished in the local Serbo-Croat dialect, as well as in Italian and Latin. The growth of interest in philosophy nurtured philosophers of South Slav origin who subsequently taught philosophy and published their philosophical works in Latin in various countries of Europe, principally in Italy, Austria and Germany.

Among the first of the South Slav humanist philosophers was Juraj Dragišić (Georgius Benignus de Salviatis), born in Bosnia in 1450 and educated in Dubrovnik, Paris, Oxford and Florence. A Franciscan monk, he was a courtier to Lorenzo di Medici and later a professor of philosophy at the University of Pisa. Philosophically, he was inclined towards Platonism, and in his polemical works he defended Pico della Mirandola as well as Savanarola. His main works were in logic (*Artis dialecticae praecepta vetera ac nova* 1520) and metaphysics (*De natura caelestium spirituum* 1499). The humanist Matija Hvale, born in what is now Slovenia, was active at the University of Vienna in the early sixteenth century.

Matija Vlačić (Mattias Flacius Illyricus) born in Labin in Istria, was educated in Germany where he became one of the leading Lutheran theologians and polemicists of the sixteenth century, firmly opposed to any compromise with Roman Catholicism. In his theological treatise *Clavis Scripturae Sacrae (A Key to the Holy Scriptures)* he not only offered a systematic linguistic exegesis of the Bible, but expounded a succinct philosophy of language and of translation. Language is a sign or image of things, that is, ‘glasses, as it were, through which we look at things’. The meaning of words is determined by the historical context in which they are used, and is thus subject to change.

This contextual view of meaning guides Vlačić's own Biblical exegesis, which Wilhelm Dilthey considered the forerunner of modern hermeneutics (1914-90 (5): 325).

Also in the sixteenth century, Franjo Petrić (Franciscus Patricius) was born in Cres, Dalmatia, educated in Germany and Italy and taught philosophy at the Universities in Ferrara and Rome. His youthful *La citá felice (The happy city)* belongs to the tradition of Renaissance utopianism exemplified by Campanella's *City of the Sun*. His philosophical system, expounded in his *Nova de universis philosophia (The new universal philosophy)*, is an attempt to synthesize Catholicism and Platonism: the light, as a spiritual force, is the first cause, the source of all movement and life in the universe; the spiritual thus permeates the whole universe and in this the human microcosm reflects the universe's macrocosmic order. In this, as in his earlier works, he rejected Aristotle's philosophy as false and godless, which resulted in his work being briefly placed on the Roman Catholic Index of prohibited books.

Rudjer Josip Bošković, (Roger Joseph Boscovich), a native of Dubrovnik who joined the Jesuit order, was educated and taught philosophy in Rome. A scientist and mathematician, he is today best known for his theory of non-extended atoms or *puncta*. In Article 164 of his *Theoria philosophiae naturalis (A Theory of Natural Philosophy)* (1763), he claims that ' Matter is composed of perfectly indivisible, non-extended, discrete points'. Having no mass, these points do not exert force in the Newtonian sense but still interact with each other. They repel each other at very small distances, reaching an equilibrium, beyond which the points attract and then again repel each other. This process is governed by Bošković's law of oscillation. Within the framework of their spatial relations, pairs of oscillating points form minute composite particles. Assemblies of these first-order particles form larger particles which, in turn, form seemingly hard bodies. The collision of impenetrable atoms, he observed, would introduce non-continuous or sudden change in their velocity (Art. 18). In order to avoid this violation of the law of continuity, he conceived atoms as non-extended and impenetrable; in contrast, observable, hard bodies are held to be extended and penetrable. Thus Bošković attempted to uphold the law of continuity which he derived from Leibniz and held to be an axiom. As L.L. Whyte (1961) shows, his deductive kinematic theory of non-extended atoms was highly influential until experimental research on the composition of atoms began early in the twentieth century.

2 Non-academic philosophy in the vernacular

At the end of the eighteenth century, the first philosophical works began to appear in as yet unstandardized South Slav vernaculars. These were works of non-academic philosophy, either popularizing philosophical ideas or presenting them in verse form. Dositej Obradović, a defrocked Serbian Orthodox monk who had attended philosophy lectures at the universities of Halle and Leipzig, was one of the first to popularize the ideas of Enlightenment. But the most original work in the vernacular was a philosophical epic in six cantos, *Luča Mikrokosma (The Ray of Microcosm)* (1845), by Petar Petrović Njegoš, Bishop-Prince of Montenegro. The epic presents a thoroughly dualistic metaphysics and a rather unorthodox cosmogony. To the duality of matter and spirit corresponds the duality of good and evil (although the source of evil is not located exclusively in the matter). The world of light borders on the world of darkness - Hades - which as a sun has its own globe of darkness. God created the heavens, the realm of light, by a stroke of shining light which destroyed the reigning realm of darkness. Satan, a duke of angels, rejected this view of the creation and rebelled against God in the name of the equality of all spirits. Upon his defeat, he was thrown into Hades while Adam (who repented of his association with Satan) and his progeny were settled on Earth, a half-way house between the heavens and Hades. Caged in the body, the human soul is governed by the conflicting laws of good and evil, and is thus condemned to the realm of tears and suffering. Both in its epic style and its pessimistic dualism, this metaphysical poem is unique in South Slav literature and philosophy.

Throughout the nineteenth century, liberal political ideas were disseminated through political pamphlets and popular encyclopedias such as Vladimir Jovanović's incomplete Politički rečnik (Political dictionary) published in Novi Sad, then in Austro-Hungary. Svetozar Marković, a socialist journalist, popularized socialist political ideas (mainly drawn from the works of Chernyshevski and Pisarev) through his newspapers and pamphlets published in Serbia. The future king of Serbia, Petar Karađorđević, while still in exile, published his (now standard) translation of Mill's *On Liberty*.

Božidar Knežević, a poor secondary school teacher, was educated at Beograd, where in 1898 he published his

visionary treatise *Principi istorije (Principles of history)*. Since everything that exists, he argued, exists only in history, history takes over the fields of other sciences and offers the highest human understanding. In addition, history binds all peoples and leads to their reconciliation and overall harmony. Knežević's optimism and belief in the progress of the human mind is tempered with his belief that the total quantity of time available to the living is limited: human civilization and even human life is thus bound to disappear. Proportion, he boldly states, is the telos of history. As both nature and humans strive after this ideal, proportion is used to explain the nature of truth, reason, good, progress, beauty, justice and freedom. Once elements achieve proportion and balance with each other, 'they live simultaneously' in a great organic whole in which one can ultimately arrive at 'complete morality, freedom, justice and truth'. Whereas academic philosophers repudiated this system as incoherent, many Serb avant garde poets and writers found in it a congenial vision of the universe in which everything, including poetry and beauty, had its own rightful place in a world striving after proportion.

3 Academic philosophy before the Second World War

From their inception, the first South Slav institutions of higher learning have established chairs of philosophy or logic: in 1863, the Beograd Great School (since 1905 the University of Beograd), in 1874 the University of Zagreb, and in 1919 the University of Ljubljana. These, as well as the universities which were founded later, have remained centres of academic philosophy.

The first professor of logic in Beograd, Konstantin Branković, based his handbooks dealing with philosophy and logic on the works of the German academic W.T. Krug. His successor, Alimpije Vasiljević, used J.S. Mill's *Logic* for the same purpose. The first philosophy professor at Zagreb, Franjo Marković (a pupil of Herbart) called for the study of Croatian philosophy, arguing that 'only the people to have acquired a homeland of thought have firmly come to own their real homeland'.

Albert Bazala, Marković's successor, was the author of *Povjest filozofije (A history of philosophy)* (1906), one of the first original works in history of philosophy in Serbo-Croat, in which Kant's work is presented as the highest achievement of modern philosophy. He continued Marković's research in the history of South Slav as well as Croatian philosophy. In his *Metalogički korjen filozofije (The metalogical root of philosophy)* Bazala argued that the human mind is not a static faculty but 'a dynamic-teleological activity'. As a dynamic activity, cognition requires that its object be sustained in time and organically related to a whole; therefore, there are no singular truths about discrete objects. In opposition to this, Bazala's colleague Pavao Vuk-Pavlović expounded a dualist theory in his *Spoznaja i spoznajna teorija (Knowledge and theory of knowledge)* (1926), where the truth-value of cognition is found in 'an experience of the logically evident' which may constitute singular truths. The relation between cognition and its objects is a subject-matter not of science but of a meta-empirical or metaphysical investigation. In defending his philosophical humanism, Vuk-Pavlović argued against Bazala's determinism and emphasized the autonomy and creativity of each human being.

France Veber (Franz Weber), the first professor of philosophy at the University of Ljubljana, was also the first academic philosopher to write in Slovene. A pupil of Meinong, his *Sistem filozofije (A system of philosophy)* developed a theory of mental presentation and of objects. The presentations (*Vorstellungen*) are the basic ingredients of all experiences, including the sensory ones. Each sensory experience can be evaluated in terms of its function either of 'attainment' or 'presentation'. The attainment is primary in sensory experiences of touch; in consequence, such experiences are closer to 'encountering reality' than any others. In visual experiences, presentation is primary, and thus reality is represented, not 'encountered'. From 1930 onwards, Veber developed a philosophical anthropology and a philosophy of God as well as a new dynamic ontology, eschewing his earlier dichotomy of object-mental presentation. Several of his students developed his earlier theory of presentation, but as the communist regime removed him from his chair in 1945, his work was ignored in Slovenia until 1987.

Branislav Petronijević from Beograd was educated in Germany and inspired by the writings of Lotze and Von Hartmann. In his principal work *Prinzipien der Metaphysik (Principles of metaphysics)* (1904), he argued that being consists of simple, discrete qualitative points which are mutually related in various ways to form a unity. His metaphysical system was thus conceived as a synthesis of the metaphysics of Spinoza and Leibniz into 'mono-pluralism'. Our immediate experience not only presents reality as is but is also the source of basic logical and metaphysical axioms (for example, the laws of identity, of contradiction and of excluded middle): all are derived from the data of immediate experience. His eclectic 'empirio-rationalist' epistemology was thus based on a

rather complex derivation of logical laws from immediate experience.

Ksenija Atanasijević from Beograd was the first recognized woman philosopher among South Slavs and a leader of Beograd's women's movement. Educated in Paris, she wrote in French and German, producing studies on the philosophy of Epicurus and of Giordano Bruno as well as on the history of South Slav philosophy. Her principal work *Filosofski fragmenti (Philosophical fragments)* (1929), attempted to reconcile her metaphysical belief in the inevitability of evil with a justification of her activist, humanist stance.

Until the outbreak of war in 1941, philosophers at Zagreb, Ljubljana and Beograd pursued a wide variety of philosophical interests. In Ljubljana, the Neo-Thomist approach had been developed since the 1860s. Additionally, philosophers in Zagreb had interest in logical positivism, in Marxism and in the contemporary philosophy of education. In Beograd, philosophers had developed interests in Neo-Kantianism, pragmatism and Bergson's philosophy, as well as in Eastern Orthodox philosophical traditions. Toma Živanović and Đorđe Tasić, Beograd professors of law, wrote in German, French and Italian on the relation of morality and law and on the fundamental grounds of law. Their colleague Slobodan Jovanović critically examined the political philosophy of Plato, Machiavelli, Burke and Marx; his essays, published in the 1930s, are minor classics of Serbian prose. Partly due to this divergence of interests, there was almost no contact or dialogue between these three academic centres during this period.

4 Philosophy after 1945

With the communist takeover in 1945, Soviet Marxism-Leninism became the official philosophy in Yugoslavia. Non-Marxist academic philosophers were faced with conversion to the official philosophy or dismissal. After the expulsion of the Yugoslav Communist Party from the Soviet-dominated international communist organization in 1948, Yugoslav Marxists were called upon to revise the official philosophy. Responding to this call, the post-war generation of Yugoslav philosophers developed a Neo-Marxist approach based on Marx's concept of praxis (mentioned in his early writings) and inspired by the writings of the Frankfurt School members as well as French existentialists (see Existentialism; Frankfurt School). The concept of praxis was chosen partly because it symbolized the Marxist commitment to bringing about social change through purposeful action.

By 1960 the orthodox historical and dialectical materialism was replaced at all Yugoslav universities by this less rigid approach. From then until the early 1980s, Yugoslav philosophers vigorously debated the nature and scope of praxis, of knowledge and truth, of freedom, alienation, socialism and humanism as well as a variety of social and political issues. These debates were carried out not only in the newly founded philosophical journals (*Filozofija* in Beograd, *Pregled* in Sarajevo, *Perspektive* in Ljubljana) but also in the mass media. During these debates the concept of praxis came to be interpreted in the following distinct but ultimately compatible ways: (1) as a free and creative activity which defines a specifically human existence - this primarily anthropological interpretation was first advocated by Gajo Petrović in Zagreb; (2) as an object-directed activity firmly anchored in human history, providing an ontological ground not only for the human universe but also for the world of nature (Milan Kangrga, Zagreb); (3) as a source and criterion of human knowledge from which one could further derive the concepts of a subject and an object (Mihailo Marković, Beograd); (4) as a social activity, aiming at abolishing and transcending the limitations of the present social reality (this axiological interpretation was advocated both by Marković and Petrović).

Yugoslav Neo-Marxists organized an international summer school of philosophy on the island of Korčula and, from 1964, published the international journal *Praxis* in Zagreb. By the late 1960s, they had changed from ardent supporters to open critics of the Yugoslav communist regime; as a result, *Praxis* was forced to cease publication and Beograd Neo-Marxists were forced out of their teaching posts in 1975. This ended the Neo-Marxist domination of Yugoslav philosophy. The dialogue which they had initiated between Yugoslav philosophers from different academic centres - the first such sustained dialogue - ended in 1983 with a quarrel between Neo-Marxists from Zagreb and Beograd concerning the publication abroad of *Praxis International* (this journal ceased in 1994).

As Praxis-Neo-Marxists cultivated interests and contacts outside Marxist philosophy, Yugoslav academic philosophers became acquainted with various non-Marxist approaches to philosophy. Among the first to promote Heidegger's approach to philosophy was Vanja Sutlić from Zagreb. In his principal work *Bit i suvremenost (Essence and contemporaneity)* (1967) he endeavoured to reinterpret the concept of praxis in Heideggerian terms:

praxis was presented as the production of *Sein* from *Dasein* (see Heidegger, M. §4). Abdulah Šarčević from Sarajevo engaged in a multifaceted critique of bourgeois society and of modernity. His *De Homine* (1986) rejected the domination of Western technology-laden thought over non-Western (such as Islamic) approaches to philosophy, and pointed out how, with its own narrow boundaries, scientific and technological progress has failed to humanize our society and has failed to humanize nature. Ivan Foht from Sarajevo developed an aesthetics in which our understanding as well as the ontological status of a work of art depends primarily on its form and not on its content. Art, he argued in his *Savremena estetika muzike (Contemporary aesthetics of music)* (1980) is a highly autonomous human activity; music, in particular, has an atemporal validity. Foht's search for an ontological definition of art, inspired in part by Ingarden, is unique in post-1945 Yugoslav philosophy.

Equally unique is the philosophical development of Mihailo Đurić from Beograd. His work in philosophy started in the early 1950s with studies in Ancient Greek philosophy and the early Wittgenstein. In the 1960s he published in Serbo-Croat a selection of Max Weber's writings, which was highly influential. In the 1970s he repudiated attempts to develop Marxist sociology or economics, arguing that Marx was neither a philosopher nor a scientist but a visionary and a critic of the inhumanity of bourgeois society. About the same time he developed an interest in Heidegger and his thesis on the crisis and the end of European metaphysics. Since the 1980s he has concentrated on the contemporary relevance of Nietzsche's philosophy: as an open workshop of thought, Nietzsche's philosophy points the way out of the crisis of metaphysics and of Western philosophy in general (see Nietzsche, F.).

In the late 1970s, Slavoj Žižek from Ljubljana developed a unique Lacanian psychoanalytic critique of totalitarian ideology and thought (see Lacan, J.). In his later writings, published in French and English, he applied this Lacanian approach to other ideologies, including the liberal-democratic one, and to popular culture and film. In his *Looking Awry* (1991) he advocated the maxim of psychoanalytic ethic 'avoid as much as possible any violation of the fantasy space of the other', and argued that nationalism is the way subjects of a given nation organize their collective enjoyment through national myths.

Interest in logical positivism and the analytic approach to philosophy developed in the 1920s in Zagreb and in Beograd. Zvonko Richtman and Rikard Podhorski from Zagreb defended a logical positivist approach to science (see Analytical philosophy; Logical positivism). In Beograd, Dragiša M. Đurić developed a highly reductive phenomenalism (which reduced the concept of time to the phenomenon of now), while Kajica Milanov discussed Frege's and the logical positivists' analyses of meaning (see Phenomenalism). In the early 1960s, Yugoslav Neo-Marxists revived interest in the analytic philosophy of meaning and meta-ethics within their Neo-Marxist framework, while Jovan Ćulum from Beograd in his *Filozofske beleške (Philosophical notes)* (1967) used analytic techniques to criticize the Hegelian and Marxist approach to philosophy. At the same time, Svetlana Knjazev-Adamović and Staniša Novaković wrote about analytic philosophy of knowledge and of science, while Aleksandar Kron started his work in symbolic logic outside any Marxist framework. In his later *Hipoteze i znanje (Hypotheses and knowledge)* (1984) Novaković argued against the view that the acceptance or rejection of hypotheses in modern science is based exclusively on empirical evidence.

In the early 1970s, analytic philosophers in Beograd engaged in a polemic concerning the analysis of moral terms. Igor Primorac forcefully defended a deontological theory. His arguments, appealing to our moral intuitions and ordinary usage of moral terms, were criticized by Knjazev-Adamović and others. In the early 1990s, she and Jovan Babić extended the debate in the journal *Theoria* to issues in normative ethics, including that of pacifism in times of war. A similar debate concerning scepticism and knowledge was sparked in 1974 by a series of articles by Neven Sesardić from Zagreb. Sesardić rejected both the argument from the evil demon and from illusion as invalid. In response, Aleksandar Pavković in his *Razlozi za sumnju (Reasons for doubt)* (1988) argued that, suitably reconstructed, these sceptical arguments could be rendered valid (see Perception, epistemic issues in). Živan Lazović from Beograd argued for the contextualism of principles in *O prirodi epistemičkog opravdanja* (On the nature of epistemic justification), an alternative to both foundationalism and coherentism which emphasizes the constitutive role of the established epistemic principles, techniques and procedures (see Justification, epistemic).

In his *Fizikalizam (Physicalism)* (1984), the first examination of contemporary materialism in Serbo-Croat, Sesardić defended the mind-body identity thesis, arguing that the replacement of intentional terms by descriptions of behavioural dispositions will facilitate scientific discovery of the relations between behavioural dispositions and

structural states of the brain (see Mind, Identity theory of). In contrast, in his *Materija, svest, saznanje (Matter, mind and knowledge)* (1990) Nikola Grahek from Beograd argued that a materialist view of the mind such as Sesardić's, faces serious problems in explaining introspection of the subject's own mental states. The debate concerning materialism and functionalism, which started in 1980s in the philosophical journals in Beograd, Zagreb and Ljubljana, appears to be continuing (see Materialism in the philosophy of mind).

Writing on the philosophy of language, Nenad Miščević (formerly from Zadar, now at Maribor) shares Sesardić's scientific naturalism. Cognitive science and linguistics, he argued in his 1987 work *Od misli do jezika (From thought to language)*, would provide the best basis for a comprehensive theory of language. Matijaž Potrč from Ljubljana has also extensively discussed current analytic approaches to the philosophy of language. Miloš Arsenijević, in his unique treatment of Zeno's paradoxes and contemporary philosophy of space and time, *Prostor, vreme, Zenon (Space, time, Zeno)* (1986), has attempted to solve the paradoxes by arguing that Zeno's premises are tenable each on their own but are not cotenable.

The break-up of Yugoslavia in 1991 has, perhaps temporarily, put an end to the debates among philosophers from Zagreb, Beograd, Ljubljana and Sarajevo. Many of them, however, continue to participate in philosophical debate outside their newly established states.

Sovereignty

In legal and political philosophy sovereignty is the attribute by which a person or institution exercises ultimate authority over every other person or institution in its domain. Traditionally, the existence of a final arbiter or legislator is said to be essential if people are to live together in peace and security. The example brought most readily to mind by the word 'sovereign' is the individual monarch, and the theory of sovereignty was at one time closely linked with the defence of monarchy. But leading theorists of sovereignty, like Jean Bodin and Thomas Hobbes, recognize that authority can be exercised by sovereign bodies of people; and later writers, like Rousseau and Austin, locate sovereignty in the people, to whom the officials of more democratic institutions are ultimately accountable.

Traditionally, too, it is deduced from the nature of the state or law that the sovereign's authority must be absolute, not limited by conditions; perpetual, not merely delegated for a time; and indivisible, not distributed between different persons or institutions. It is further deduced that the sovereign must be independent from external domination as well as internally supreme. All these inferences have been subjected to criticism, not least because they can be difficult to reconcile with the actual practice of states and legal systems.

1 Sovereignty and utility

It seems to have been no coincidence that the two foundation texts of the modern theory of sovereignty were both published in conditions of civil conflict, Jean Bodin's *Six livres de la république* (1576) at the height of the French wars of religion, Thomas Hobbes' *Leviathan* (1651) in the immediate aftermath of the English Civil War (see Bodin, J. §2; Hobbes, T.). For the early appeal of the concept delineated in these works lay largely in its apparent solution to the problem of anarchy. Hobbes' treatment is particularly illuminating in this respect. He begins by arguing that given certain features of human nature the life of people outside the commonwealth is bound to be, as he famously put it, solitary, poor, nasty, brutish and short. To live in peace and security people have to submit to a power that is able to compel them to fulfil their obligations.

To begin with people live in small family units, but their existence at this stage is characterized by internecine feuds, not by peace and security. The emergence of more powerful groupings of individuals or families may achieve a greater measure of stability, but Hobbes maintains that however large and powerful these groups may be they cannot ultimately enable people to live peacefully and securely. The balance of power may shift through regrouping, and within each group people will continue to pursue their individual interests. The appearance of a common enemy may draw them together, but only temporarily, and even then they will argue about the best use of their resources. In short, the collective life of people will of itself be no different from the solitary life.

To live in peace and security people need to establish a commonwealth, and for Hobbes that means submitting to a 'Soveraigne Power'. Each subject individual must surrender their personal power to do what they think best for their own preservation and accept the determination of another, until one person alone is left with the authority to decide what should be done. That person, whether an individual or an assembly of individuals, will then have the sovereign power necessary to coerce the rest of the people into fulfilling their obligations. The person may in fact have been the head of a family or larger grouping, but their judgment will now be final and decisive, and their exercise of power will not be limited to the duration of an emergency. Their sovereignty will continue for as long as they are able to protect their people, and the people will have peace and security for as long as they have a sovereign.

2 Sovereignty and logic

If it was this sort of argument for the expediency of submitting to a final arbiter that first attracted exponents of sovereignty, and if this sense of the practical necessity of an ultimate authority has remained important throughout the history of the concept, a more prominent feature of its presentation has been an emphasis on logical analysis. Hobbes himself was committed to a mode of exposition that starts with the definition of a term, then proceeds to explore its implications. So from the definition of sovereignty it may be deduced that it must be absolute and indivisible. It must be absolute because conditions could only be meaningfully imposed on a sovereign's exercise of power if there were some other person with authority to determine when they were being violated, in which case

the sovereign would not be the final arbiter. Similarly sovereignty must be indivisible because otherwise there might be disagreements between the different bearers of authority, in which case there would again be no final arbiter.
